TECHNICAL INFORMATION (TI)

With the following Technical Information, or TI, we are living up to our reputation of supporting you with current information and customised solutions in everyday business.

In the following more than 260 pages, you will find all relevant information related to fastener and fixing technology. This, for example, includes measurement data sheets and tables with locking torque and pre-loading for assembly. Moreover, there is information on current anti-corrosive systems and new standardisation in the field of stainless steels. In addition, there is an overview of guidelines and regulations, as well as changes to standards, as valuable orientation when selecting products.

REYHER's contribution to standards bodies provides a forum for technical observation of the market, supplying information in good time regarding new technologies and customer-specific requirements.

MEMBER OF DIN

Today, REYHER is helping to shape tomorrow's products!

Table of contents TI

Table of contents TI

Standards conversion DIN → ISO/EN

The conversion of some national DIN standards to ISO or EN standards is (was) done with the aim of deconstructing trade barriers in international goods exchange and harmonising the technical rules in the common single European market.

Table 1 shows the ISO/EN standards for product standards and the most important thread and basic standards according to the corresponding DIN in ascending order (as of: 10/2019).

Table 2 (next page) shows the EN and DIN standards according to the corresponding ISO in ascending order.
The tables also include draft standards and withdrawn standards.

– ISO/EN standard not yet known (as of 10/2019)

( ) Transitional standards (dimensions identical with ISO)

* withdrawn DIN standard without replacement, because, for example, technically reworked
(On issue of DIN EN-/DIN EN ISO standards the corresponding DIN/DIN ISO are/were withdrawn)

Legend for table 2

HV	high strength steel
Csk.	countersunk
Rcsk.	raised countersunk
CT/FT	coarse pitch thread/fine pitch thread
CH/TC/CD/CP	with flat point/with cone point/with dog point/ with cup point
Hex.	hexagon
CR	cross recess
MP	Mechanical Properties
S/H/L	standard/heavy/light version
Ww	Withworth
TDC	technical delivery conditions

Standard types, relations, publishers:

DIN National German standard (Deutsches Institut für Normung). DIN standards shall still be given for the products/services for which there are no ISO/EN standards and no standardisation necessity.

ISO International Standardization Organisation

DIN ISO National German issue of an unmodified, adopted ISO standard

EN **E**uropean **N**orm (CEN = Comité Européen de Normalisation). In general, existing ISO standards should be adopted as EN standards with the ISO standard number → EN ISO. If this does not happen at European standards levels, independent EN standards shall be generated with EN standard numbers which are different to those of the ISO.

DIN EN National German issue of an unmodified, adopted EN standard.
According to the resolution of the European Council, EN standards are to be adopted unmodified and immediately by the EU member states and the corresponding national standards are to be withdrawn.

EN ISO European standard issue which was adopted unmodified by ISO (EN and ISO standard numbers are identical – the earlier practice of "ISO number + 20,000" has not been in use since Jan. 95. Standards still in use according to this mode are to be converted accordingly). **The description is carried out according to ISO.**

DIN EN ISO National German issue of an unchanged EN standard adopted by ISO. The article naming is done according to ISO.

Publisher and author of the standards for "Mechanical fasteners" is the German National Standards Organisation (DIN - Deutsches Institut für Normung e.V.), Berlin, www.fmv.din.de. Reference to the standards sheets from Beuth Verlag GmbH, Burggrafenstrasse 6, 10787 Berlin, www.beuth.de, Fax +030 2601-1260

Table 3: Overview of standards conversion DIN → ISO/EN – Screws/bolts with drive, set screws, screws/bolts without drive

Article group	DIN	→ ISO/EN	Dimension range	Changes	Labelling
1. Screws/bolts, with ISO/EN standards 	**558 931 933 960 961**	**ISO 4018 ISO 4014 ISO 4017 ISO 8765 ISO 8676**	M 10, 12, 14, 22	new ISO wrench sizes	ISO standard numbers
			all other ∅	none = DIN and ISO identical	1. ISO standard numbers 2. DIN standard numbers
	601 Mu with nut DIN 555	**ISO 4016 Mu** with nut ISO 4034	M 10, 12, 14, 22	screws: new ISO wrench sizes nuts: new wrench sizes acc. to ISO + ISO heights	ISO standard number
			other ∅ up to M 39	screws: none = DIN and ISO identical nuts: new ISO heights	1. ISO standard numbers 2. DIN standard numbers
			other ∅ greater than M 39	none = DIN and ISO identical	
	6914	**EN 14399-4**	all ∅	modified calculation of clamping length	EN standard number
	7999	**EN 14399-8**	all ∅	lubrication	
	**912**	**ISO 4762 (CT) ISO 12474 (FT)**	all ∅	none	1. ISO standard number 2. DIN standard number
	**6921**	**EN 1665 (EN 1662 – light series)**	all ∅	marginally increased head heights and wrenching height, property class 12.9 discontinued	ISO standard number
			from M 10	new wrench sizes	
	**7991**	**ISO 10642**	M 22, M 24	dimensions discontinued	
			all other ∅	modified head hights + head ∅- adjusted shaft lengths	ISO standard number
2. Set screws with ISO/EN standards					
	**417**	**ISO 7435**	all ∅	none	1. ISO standard number 2. DIN standard number
	**427**	**ISO 2342**	all ∅	slight differences in slot geometry -> no functional impairment	
	**551**	**ISO 4766**			
	**553**	**ISO 7434**	all ∅	none	
	**913**	**ISO 4026**			
	**914**	**ISO 4027**			
	**915**	**ISO 4028**			
	**916**	**ISO 4029**			
3. Hexagon head screws without ISO/EN standards	**561 564**	**– –**	∅ M 12, 16	new ISO wrench sizes	DIN standard numbers + wrench size specifications
			all other ∅	none	DIN standard numbers
	609 ~ 610	**– –**	∅ M 10, 12, 14, 22	new ISO wrench sizes	DIN standard numbers + wrench size specifications
			all other ∅	none	DIN standard numbers
	**7968 Mu 7990 Mu** with nut DIN 555	screw: – with nut ISO 4034	M 12, (22)	screws: new ISO wrench sizes nuts: new ISO WS + ISO heights	DIN standard numbers + wrench size specifications
			all other ∅	screws: none nuts: new ISO heights	DIN standard numbers
4. Screws/bolts without drive and without ISO/EN standards **– with hexagonal nuts with ISO/EN standards** 	**186/261 Mu 525 Mu 529 Mu 603 Mu 604 Mu 605 Mu 607 Mu 608 Mu 7969 Mu 11014 Mu** with nut DIN 555	screw: – with nut ISO 4034	∅ M 10, 12, 14, 22	screws: none nuts: new ISO WS + ISO heights	DIN standard numbers + wrench size specifications
			all other ∅	screws: none nuts: new ISO heights	DIN standard numbers

① Labelling with ISO and DIN standard numbers are valid for the transition period, later only the ISO standard number will apply.

Table 4: Overview standards conversion DIN → ISO/EN – Hexagon/square nuts
– Hexagon nuts with prevailing torque element

Article group	DIN	→ ISO/EN	Dimension range	Changes	Labelling
1. Hexagon nuts with ISO/EN standards 	**439-1** (A = without chamfer) **439-2** (B = with chamfer)	**ISO 4036** **ISO 4035** = coarse pitch thread **ISO 8675** = fine pitch thread	∅ M 10, 12, 14, 22	new ISO wrench sizes (no height change)	ISO standard number
			all other ∅	none = DIN and ISO identical (no height change)	1. ISO standard number 2. DIN standard numbers
	555 **934** Property classes 6, 8, 10 Property class 12 Property classes 6, 8, 10	**ISO 4034** (ISO type 1) **ISO 4032** = coarse pitch thread (ISO type 1) **ISO 4033** = coarse pitch thread (ISO type 2) **ISO 8673** = fine pitch thread (ISO type 1)	∅ M 10, 12, 14, 22	new ISO WS + ISO heights	ISO standard numbers
			other ∅ M 5 – M 39	new ISO heights (no wrench sizes change)	
			∅ less than M 5 ∅ over M 39	none = DIN and ISO identical	1. ISO standard numbers 2. DIN standard numbers

Overview of standards DIN → ISO: Bolts, pins, washers for bolts

The most important changes are listed in table 9. For some articles, the DIN and ISO versions are identical or the minor changes are hardly relevant to the function at all so that exchangeability is possible.

The conversion is done in an appropriate transition time according to the availability from manufacturing or according to the customer's wishes. Further information on request.

Table 9

Article group	DIN	ISO DIN ISO DIN EN ISO	The most important changes
Taper pins, parallel pins 	1	2339	length l new according to ISO **incl.** round end (previously according to DIN **excl.** round end)
	7	2338	length l new according to ISO **incl.** round end (previously according to DIN **excl.** round end) types A, B, C (type A/tol. m 6 new with chamfer/round end)
	6325	8734	new: type A with chamfer/round end, fully hardened (for the most part identical with DIN 6325) type B with champfer, case hardened
	7977 7978	8737 8736	no serious changes
	7979/D	8733 8735	DIN 7979/C ~ ISO 8733 [unhardened] DIN 7979/D ~ ISO 8735/A [fully hardened], lower hardness for ISO
Grooved pins 	1470 1471 1472 1473 1474 1475	8739 8744 8745 8740 8741 8742	length l new according to ISO **incl.** round end (previously according to DIN **excl.** round end)
	–	8743	new: grooved pins, half-length centre grooved
	1476 1477	8746 8747	type A = no serious changes additional: type B with pilot end
Spring-type straight pin	1481	8752	regular finish to ∅ of m 8 mm with 2 chamfers (previously to a ∅ of m 6 mm)
	7343 7344 7346	8750 8748 13337	no serious changes
	– –	8749 8751	new: pins, grooved pins: shear test new: spring-types straight pin, light duty
Split pin 	94	1234	no serious changes
Clevis pin 	1443 1444	2340 2341	partially other nominal lengths length tolerances changed
	1433 1434 1435 1436	– – – –	these DIN standards were withdrawn ISO standards are not planned
Washers for pins 	1440	8738	Some outer ∅ and thicknesses changed (in general not in danger of being replaced)
	1441	–	no ISO standard planned

Overview of standards conversion DIN → ISO: Thread srews and tapping screws

ISO standards for thread screws and tapping screws include the following changes different to DIN standards:

– new countersunk angle for tapping screws with countersunk/raised countersunk head = 90° according to DIN 66/ISO 7721 (previously 80°)

– tapping screws: cancellation of diameter ST 3.9

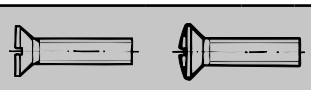
– partial changes to the head dimensions

The tables show the standard numbers change DIN : ISO (Tab. 10) and head dimension changes DIN : ISO (Tab. 11–13)

Table 10: Standard numbers change DIN : ISO

Article group	DIN	ISO	The most important changes
Thread screws 	84	1207	no serious changes
	85	1580	no serious changes
	963	2009	minor differences in head height and head diameter (see Table 11)
	964	2010	
	965	7046-1, -2	
	966	7047	
	7985	7045	no serious changes
Tapping screws 	7971	1481	no serious changes
	7972	1482	changed countersunk angle (DIN = 80° : ISO = 90°) minor differences in head height and head diameter (see Table 12)
	7973	1483	
	7976	1479	minor differences in the head height – no risk of being replaced (see Table 13)
	7981	7049	no serious changes
	7982	7050	changed countersunk angle (DIN = 80° : ISO = 90°) minor differences in head height and head diameter (see Table 12)
	7983	7051	

Table 11: Slotted and cross recessed countersunk head screws with metric thread



Metric screws

1.3	1.7	2.1	2.3	2.5	3	3.4	3.8	–	–

Note on countersunk head screws with metric threading

When countersinking according to ISO 15065 (for ISO countersunk heads) screws can also be used according to DIN 963 – 966.
These merely lie a little deeper in the countersink.
If the countersink is executed according to the withdrawn DIN 74-1:1980, a protrusion may, under certain circumstances, be visible when using ISO countersunk heads above the component part (especially with the diameters M 3.5, M 4 and M 8).

Product information: Disc springs DIN 2093

According to DIN 2092 and DIN 2093, disc springs are cone-shaped discs which can be stressed along the axis. Compared to other spring-types, these fully concentric bending springs with symmetric-rotation cross section have low spring deflection with high spring power. The characteristic line of the disc springs depends to a large extent on the relationship of the free spring height [h0] to the flatness and disc thickness [t]. This is why the characteristic line is split into three series.

Each series is split into three groups according to their thickness. These groups differentiate themselves from each other with various production processes.

Table 1: Names

D_e	Outside diameter
D_i	Inside diameter
t	Thickness of the individual disc
l_0	Construction height of the unstressed individual disc
s	Spring deflection of the individual disc
h_0	Information parameter (spring deflection up to the height for disc springs without bearing surface); $h_0 = l_0 - t$

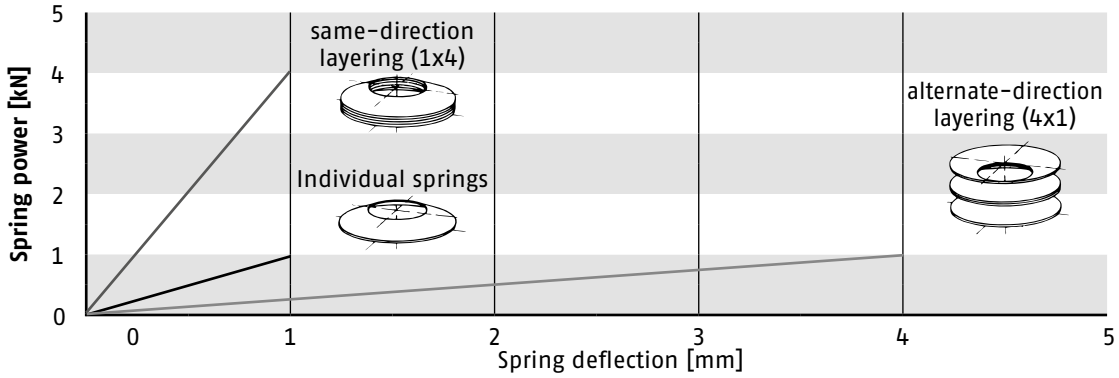
Table 2: Difference according to series

Series	Factor from $\frac{D_e}{t}$	Factor from $\frac{h_0}{t}$
A	~ 18	~ 0.4
B	~ 28	~0.75
C	~ 40	~ 1.3

Table 3: Difference according to groups

Group	Thickness t	Manufacture/Processing
1	< 1.25 mm	cold-formed (punched), edges rounded, without bearing surface,
2	1.25 – 6 mm	cold-formed finely cut, D_e and D_i turned, without bearing surface
3	> 6 mm	cold or hot-formed, turned on all sides, with bearing surface,

Same-direction layering, alternate-direction layering or a combination of the two let disc springs be formed into columns with freely configurable characteristics. If, for example, a spring column is made up of four alternate-direction individual disc springs with the same geometry, the spring deflection increases fourfold in comparison with individual springs. With a spring packet of four same-direction layering springs, the spring power increases fourfold in relation to individual springs.



The materials named in EN 10083, EN 10089 and EN 10132-4 are permitted for disc springs
(standard is the material 1.8159 – 51 CrV 4),
C steels, however, only for Group 1 disc springs.
The disc springs are delivered hardened and tempered with a hardness of 42-52 HRC (Group 1 disc springs: 425 HV10 to 510 HV10).
The standard surface is coated in phosphate and oiled. Many additional surfaces for increasing corrosion-resistance, like for example, mechanical galvanization or zinc-flake coating, are possible.

Stainless steels are also used as disc spring material. Compared with the standard, these special springs can have different, but always lower spring power.

Disc springs DIN 2093 – in stock

- from Cr/CrV alloy stainless steels
  (REYHER catalogue ➔ green pages 227)

  (REYHER catalogue ➔ blue pages 525)

Disc springs – available on request

- Disc springs in special dimensions
- Disc springs in special materials
- Disc springs with special coatings

Taking into account a high safety factor in relation to the minimum breaking strength, the lifting eye bolts according to DIN 580 and the lifting eye nuts according to DIN 582 have the load-bearing capacities as indicated in table 1. The load-bearing capacity values apply for steel C15 E and stainless steel A2/A4 without restriction in a temperature range of -20 °C to +200 °C.

Lifting eye bolts and lifting eye nuts are considered load-carrying equipment according to the 2006/42/EC Machinery Directive and are subject to CE labelling. Furthermore, they must show a specification of the minimum carrying force (WLL) as well as the specification of the material if required for safe usage. Furthermore, a marking of an arrow must be present (picture 1), so that the user can tell that the WLL specified on the product only applies in the direction of the axis.

Subsequent colour-coded marking of lifting eye bolts and nuts (especially in red) is to be avoided so that they are not mistaken for high-strength suspension points.

User information for lifting eye bolts DIN 580

Eye bolts conforming to DIN 580 are primarily intended as permanent attachments on equipment such as motors, control cabinets, gear boxes, etc. for their transportation. When used as temporary attachments on objects to be transported such as large tools, the next largest thread size should be used.

The safety working load values in table 1 are based on the following conditions:

- the eye bolt is firmly screwed down
- the collar sits evenly on the contact surface
- the material of the equipment is capable of accommodating the stresses induced without any deformation liable to impair safety
- tapped holes have a threaded length sufficient to ensure that the eye bolt shank is fully engaged and the collar fully seated.

The capacity specified in the second line of table 1 applies up to an inclination angle of 45°. The capacity specified in the third line applies for laterally inserted eye bolts (eye nuts) up to an inclination angle of 45° in all directions in regard to the eye level. Lateral pull shall not be applied (see picture 2).

Before being used, lifting eye bolts should be checked for correct seating and apparent damage (e.g. corrosion, deformation).

Deformed eye bolts should be discarded and not be reinstalled.

In eye bolt assemblies with clearance hole, a nut (no thin nut) should be screwed on completely and firmly.

In case of sufficient thread length of the bolt, the additional use of a washer is recommended.

Product information: Lifting eye bolts and lifting eye nuts

User information for lifting eye nuts DIN 582

Eye nuts conforming to DIN 582 are primarily intended as permanent attachments on equipment such as e.g. control cabinets etc. for their transportation. When used as temporary attachments on objects to be transported, the next largest thread size should be used.

The safety working load values in table 1 are based on the following conditions:

- the eye bolt is firmly screwed down
- the collar sits evenly on the contact surface
- the length of the bolt thread is sufficient and the material is capable of accommodating the stresses induced without any deformation liable to impair safety,
- the material of the bolt on which the eye nut is to screwed is of adequate strength.

In eye nut assemblies with clearance hole a washer should be used.

The capacity specified in the second line of table 1 applies up to an inclination angle of 45°, the capacity specified in the third line applies for laterally inserted eye nuts (eye bolts) up to an inclination angle of 45° in all directions in regard to the ring level. Lateral pull shall not be applied (see picture 3).

Before being used, lifting eye nuts should be checked for correct seating and apparent damage (e.g. corrosion, deformation).

Deformed eye nuts should be discarded and not be reinstalled.

1. Standards

The following standards apply for "wire thread inserts for the metric ISO thread"

- DIN 8140-1 dimensions, technical specifications
- DIN 8140-2 helical coil threads for inserts, thread tolerances
- DIN 8140-3 gauges and gauge sizes

These standards apply for ISO metric coarse pitch threads and fine pitch threads.

Details for additional deliverable thread types (BSW/BSF, UNC/UNJC/UNF/UNJF, GAZ, BSP) are available upon request.

2. Field of application/materials/properties

- Initial use: for heavy-duty and long-lasting inside threads partly from metallic and non-metallic materials
- Use during repairs/follow-up work: as a replacement for unusable threads (= damaged/worn).

The particular properties of wire thread inserts are

- reduced inclination for cold welding with screwed fastenings
- mostly constant friction coefficient
- good temperature and corrosion resistance
- with profile B "locking" (➜ 4) additional resistance against independent loosening of the screwed fastenings thanks to increased frictional locking in the thread.

Beyond the standard material in stock "Stainless steel 18.8 (A 2)", wire thread inserts from special materials are deliverable for particular usage requirements ➜ Table 1.

Tabelle 1: Materials for various fields of application

Material	Max. temperature	Options for coatings	Applications
Standard material Stainless steel 18.8 (A 2)	425 °C (short-term) 315 °C (longer periods)	Dry lubrication Cadmium plating Silver plating Zinc plating Tin plating	All standard applications for all materials
AISI 304 (1.4301) AISI 302 (1.4310)			Special use – resistant to acid, rust, high temperatures, non-magnetic
Special stainless steel AISI 304L, 316, 316L, 316Ti, 321	Up to 400 °C over longer periods		
Phosphorous bronze	300 °C (short-term) 250 °C (longer period)	Cadmium plating	Copper parts - resistant to certain electrolytic processes
Inconel x 750 Nc 15 Fe Nba	750 °C (short-term)	Silver plating	Thermal power stations Astronautics Aviation Turbo compressor
Nimonic 90 Nc 20 C 18 Ti	538 °C (longer periods)		

3. Manufacture

The thread inserts are manufactured from a wire with rhombus-shaped cross-section. After the winding process, they have two threaded profiles, one outside for the insertion into the tool's receiving thread according to DIN 8140-2 and one inside (after insertion) for receiving a screw thread.

4. Types

According to DIN 8140-1, the profiles are differentiated according to:

- Type A = cylindrical shape* for coarse and fine threads.
- Type B = "locking" (like type A, but with centrally positioned, polygon, elastic windings (➜ 2)
  (type B thread inserts are identifiable by their red colour).

*The new generation of the "Type SR" AMECOIL thread inserts is designed in such a way that insertion is now easier and safer, thus increasing productivity.

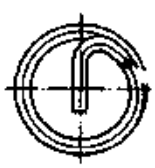
5. Drive systems for insertion

DIN 8140-1 shows an engaging tang as the drive system, which is to be removed at the groove using a tang breaker after insertion.
AMECOIL thread inserts, for example, have this drive system.

6. Determining the nominal length

The nominal lengths of the threaded inserts to be chosen are,
a) dependent on the tool material and,
b) dependent on the strength class of the screw
(recommended nominal lengths ➜ DIN 8140-1, Table 1).

Type A	Type B
	
	



with engaging tang and groove according to DIN 8140-1 (z.B. AMECOIL)

7. Dimensions/Measuring techniques during acceptance inspection

In the order text, the following dimensions are to be specified (example M 10x15):

- the use/inside thread required after insertion – e.g. M 10
- the chosen nominal length according to DIN 8140-1, Table 1, l_1 – e.g. 15 (= 1.5 d).

In as-delivered condition, only the outside diameter and the number of windings are measurable during acceptance inspection (➔ Table 2) – the nominal length l_1 is first determinable in inserted condition.

Tabelle 2: Dimensions – outside Ø and winding count in as delivered condition

8 POINT LED

Description of assembly symbols

In case of profiles with closed ends, they cannot be inserted subsequently. Nuts for T-slots must be inserted from the slot end.

Swivel-in nuts can be inserted into the slot at any position. Thus, they are perfectly suitable for assembly in existing structures. However, T-slot and nut for T-slot sizes have to match. The nut can be swiveled into the slot at any position.

Screw-in type nuts can be inserted into the slot at any position. They are also perfectly suitable for assembly in existing structures. Rhomboidal and hammer head nuts have this property. This is also applicable for hammer head bolts. For this type of nuts, inserting aids such as e.g. slot in the T-nut, thread pitch error, marking or plastic tang in the thread are helpful.

Fixing systems

Fixing systems are intended to prevent displacement of nuts before, during and after assembly as well as during disassembly, particularly in case of perpendicular mounting rail. The fixing systems can be combined with the individual assembly types. The nuts can be fixed in the T-slot so as to facilitate assembly.

Versions

Nuts without guide step for T slots usually show greater allowance for the bolts to be fixed in lateral direction. They are particularly suitable for situations, in which the connecting parts cannot be prepared accurately.

Nuts with guide step for T-slots are centred in the rail by their step. Therefore, these nuts can also be used in rails, in which the lower groove width is considerably larger that the nut width. In addition, the step facilitates assembly and, due to the step, more usable thread leads are available, which helps increase the nut's load bearing value.

Fixing component

Article number	Description		
87010.011	T-slot nuts, (M 4/M 5) profile 5 with guide step and spring-loaded ball, zinc-plated steel		87010.012	T-slot nuts, (M 4/M 5) profile 5 without guide step and with spring-loaded ball, zinc-plated steel		87011.013	T-slot nuts, (M 5/M 6) profile 6 with 6 mm external guide step and spring-loaded ball, zinc-plated steel		87012.011	T-slot nuts, (M 6/M 8) profile 8 with guide step, zinc-plated steel

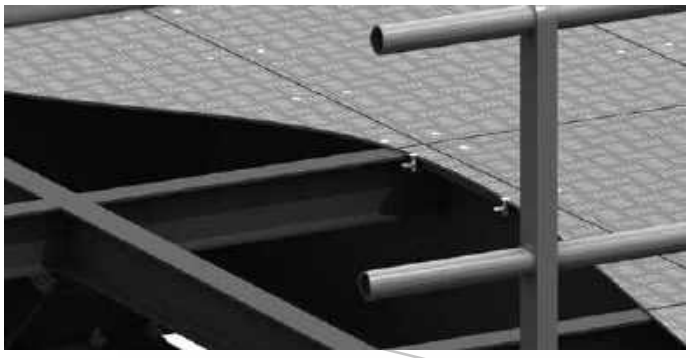
Areas of application

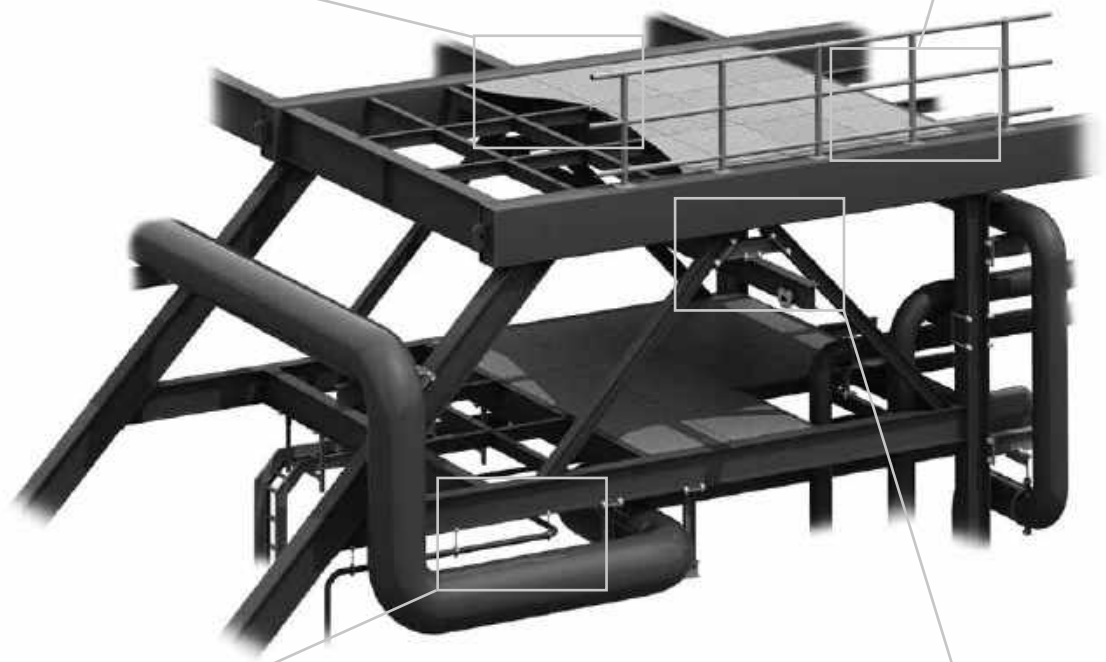
Floor Fixings

It is now possible to connect steel flooring to supporting steelwork without on-site drilling or welding for a fast, low cost operation. Lindapter fixings allow installation to be carried out safely from above, often by one person, without elevated floors thus significantly reducing costs.



Cavity Fixings

The legendary Hollo-Bolt® and Lindibolt® allow fast, cost-effective connections to SHS and other hollow sections, or conventional steelwork where access is available from one side only. The Hollo-Bolt can be used as a primary structural connection as detailed in the SCI/BCSA publication 'Joints in Steel Construction – Simple Connections'. Plug-like fixing element for hollow profiles, pipes and other constructions which are difficult to access from the rear.



Support Fixings

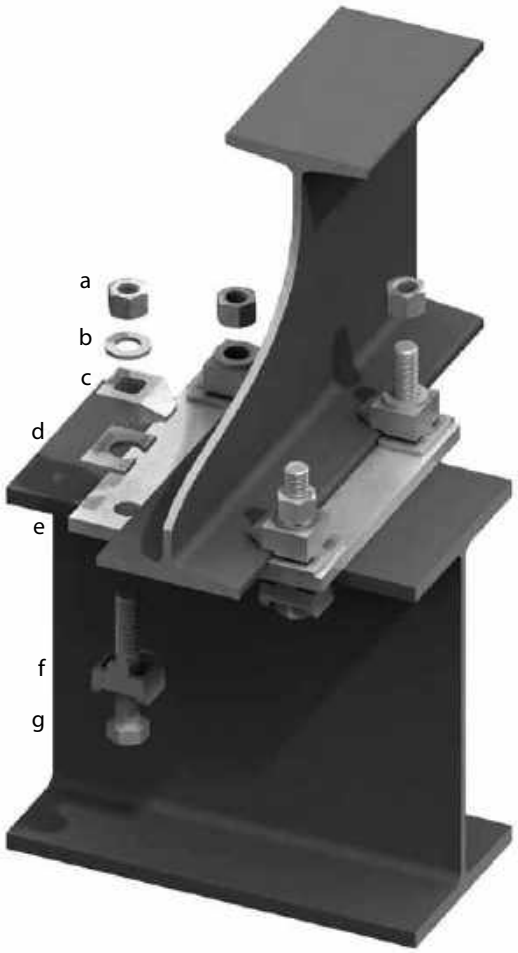
Lindapter provides easy-to-install solutions for supporting building services from structural or secondary beams, including: the suspension of HVAC equipment, pipe work, fire protection/sprinkler systems, suspended ceilings and electrical equipment.

Steelwork Fixings

Lindapter has pioneered the development of steelwork clamping systems for over 75 years, and continues to innovate with their unique and proven concept: eliminate the need to drill or weld, to reduce installation time and labour costs. Lindapter steelwork fixings and girder clamps transform this concept into reality and are ideal for new construction and the refurbishment of existing structures.

Components of a girder clamp

1. **hexagon nuts, property class 8**
   according to DIN 934 (ISO 4032)
2. **washers**
   according to DIN 125 (ISO 7089)
3. **Lindapter clamps**
   Denpending on the application, different clamps may be used, such as e.g.: A, B, BR, AF, LR, LS, D2, or D3.
4. **Packing piece**
   In combination with the above-mentioned clamps these parts increase the tail length to enable the product to sit correctly on the beam.
5. **Location plate**
   This is an essential part of the girder clamp assembly that enables all the components to be located in the correct position. The dimensions depend on the Lindapter type, beams and loads.
6. **Lindapter clamp**
   Same as no. 3.
7. **hexagon bolts, property class 8.8**
   according to DIN 931 (ISO 4014) or DIN 933 (ISO 4017)



Loads

The table beneath shows tensile and frictional load capacities for a standard four-bolt girder clamp using 4 bolts and 8 Lindapter clamps. Lindapter will gladly prepare a customized parts list for any girder clamp connection based on the following customer details:

- Load per connection
- Size and type of both beams
- Flange widths
- Flange thicknesses
- Angle of crossover
- Inclination between beams

Clamps Type A,B, and LR

Screw (Property class 8.8)	Permitted load (5:1 safety factor) Tensile force / 1 screw kN	Tensile force / 2 screw kN	Tightening torque* Nm
M 8	1.0	–	6
M 10	1.5	–	20
M 12	4.5	0.9	69
M 16	8.5	1.7	147
M 20	13.2	2.6	285
M 24	19.0	3.8	491

* Bolts and nuts not lubricated

Clamps Type AF and AAF

Screw ø	Property class	Tensile force / 1 screw (5:1 safety factor) kN	Shearing force / 2 screw (2:1 safety factor) Beam coated kN	Beam zinc-plated kN	Tightening torque Non-lubricated Nm	HV Set* Nm
M 12	8.8	8.5	3.4	3.9	90	–
M 16	8.8	16.0	8.0	10.0	240	–
M 20	8.8	26.3	13.0	16.0	470	–
M 24	8.8	40.0	24.0	30.0	800	–
M 12	10.9	10.0	4.0	5.2	130	100
M 16	10.9	19.5	11.0	12.0	300	250
M 20	10.9	30.0	20.0	25.0	647	450

* K class K1

Note:
All loads are based on actual test data having a safety factor for friction against slip and for tensile against ultimate failure.
Use of lower safety factor is not recommended.

Approvals

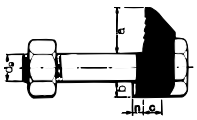
Lindapter girder clamps, types A and B, in sizes from M 12 to M 24 have been approved as construction products via ETA-13/0300.
For use of girder clamps under dynamic load (e.g. crane runways) the applicable calculation provisions according to the approval notification shall be observed.

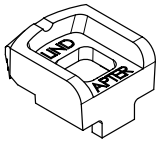
**You can find more detailed information in the Lindapter catalogue.
This can be requested directly from REYHER or downloaded from www.lindapter.de.**

Girder clamps

Type A and B

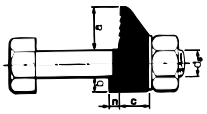
Type A
(R 82001)

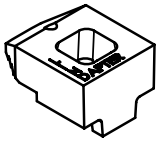




ETA CE

Type B
(R 82002)

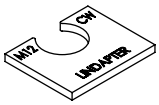




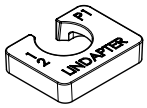
ETA CE

Accessories for type A and B

Type CW
(R 82011)

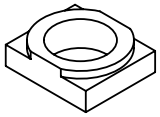


Type P1k/P2k
(R 82012/82013)



Washers for adjustment of different flange thicknesses

Type W
(R 82021)



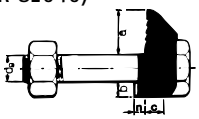
Recess filling plates for type A

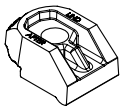
Application examples

Clamps for static and dynamic loads with adjustment of flange inclinations of up to 8°

Girder clamp type AF

Type AF
(R 82040)

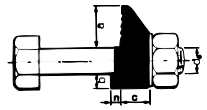




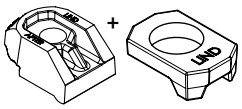
ETA CE

Accessories for type AF

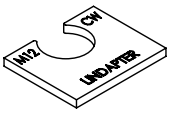
Type AF + AFW
(R 82040 + R 82041)



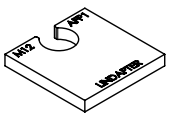
ETA CE



Type AFCW
(R 82042)



Type AFP1/AFP2
(R 82043/82044)



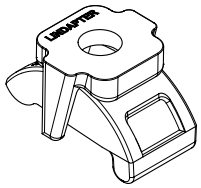
Washers for adjustment of different flange thicknesses

Application examples

Clamps for high friction loads with adjustment of flange inclinations of up to 10°.
Type AF force is preferably combined with type CF.

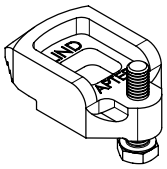
Girder clamp of type LR and D2

Type LR
(R 82010)



ETA CE

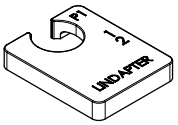
Type D2
(R 82007)



ETA CE

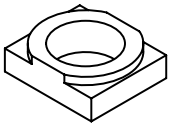
Accessories of type LR and D2

Type P1L/P2L
(R 82015/82016)



Washer for adjustment of different flange thicknesses

Type W
(R 82021)



Recess filling plates for type D2

Application examples

Type LR
Adjustable two-part clamp with large clamping range and anti-turn locking device. Adjustment of flange inclinations of up to 15°.

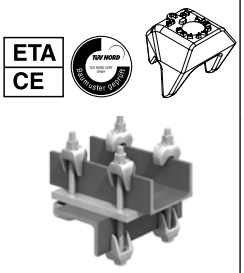
Type D2
Clamp with adjustable screw for large clamping range and anti-turn locking device. Adjustment of flange inclinations of up to 5°.

(R = REYHER article number)

Information on the dimensioning and loads can be found in the Lindapter catalogue.
This can be requested directly from REYHER of downloaded from **www.lindapter.de**.

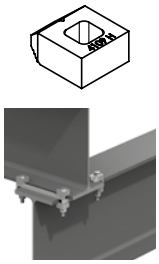
Girder clamps – special clamps

Type CF
(R 82045)



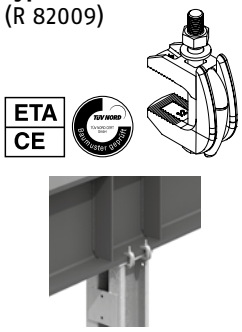
Preferably used in connection with type AF. This type hooks around the flange edge of the profiles.

Type BSNT
(R 82003)



Special clamps for the assembly of girders – flange on flange. The inner plate is replaced by a flat steel frame which is welded onto the clamp.

Type F9
(R 82009)



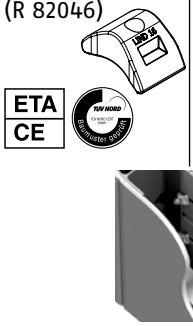
Flange clamp for parallel girders with identical width. Not suitable for tapered flanges.

Type BR
(R 82048)

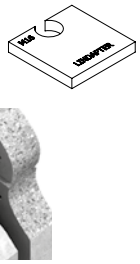
Accessories
Type CW/P1K/P2K

A versatile clamp for beams or rails. The skirt prevents the clamp from rotating during installation. Also suitable for slotted holes. Suitable for flange inclinations of up to 8°.

Type LS
(R 82046)



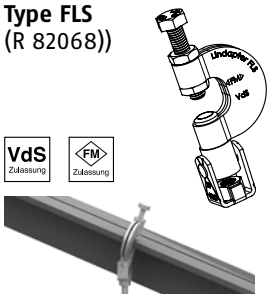
Accessories
Type LSP2
(R 82047)



Adjustable single-part clamp with large clamping range. Serrated cams help secure against twisting on the flange. Wide cam for application in slotted holes. Suitable for flange inclinations of up to 10°.

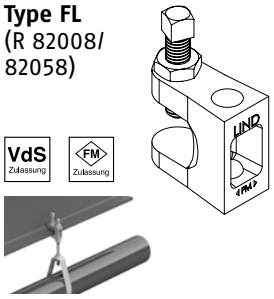
Support fixings

Type FLS
(R 82068))



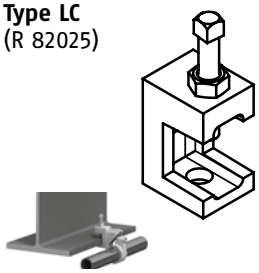
Girder clamp with swivel for use with parallel and inclined flanges.

Type FL
(R 82008/ 82058)



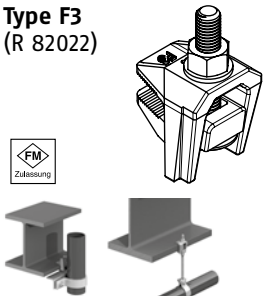
Girder clamp for parallel and inclined flanges with clearance hole or connection thread.

Type LC
(R 82025)



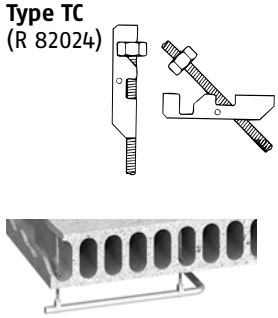
Girder clamp for parallel and inclined flanges with connection thread parallel and perpendicular to the adjusting screw.

Type F3
(R 82022)



Two-part flange clamp with large clamping area for use on parallel flanges.

Type TC
(R 82024)

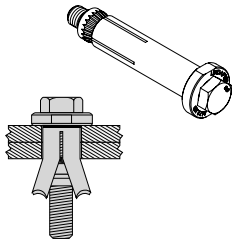


Toggle fixings for mounting to hollow ceilings or steel profiles.

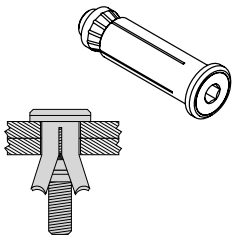
Cavity fixings

Examples of use

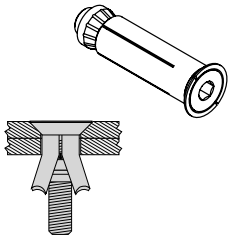
Type HB – Hexagon head
(R 82031)

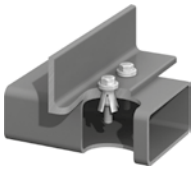


Type HBCSK – Countersunk head
(R 82031)



Type HBFF – Flush Fit
(R 82031)



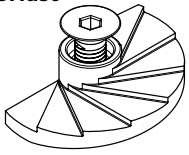


Plug-like connecting element, suitable for hollow sections, tubes and where access is available from one side only.

Floor fixings

Examples of use

Type FF – Floorfast
(R 82019)



Eccentric stepped web of this clamp is suitable for floor fixings. After fixing the Floorfast to the baseplate, the plate can be assembled from the top. The clamp will automatically lock in the right position when torque is applied.
Lloyds' Register Type Approval covers clamping force and vibration.

(R = REYHER article numbers)

When selecting the right plug or anchor for all purposes of use the following important factors need to be taken into consideration – here is some advice to help you make your choice:

1. The building material (anchoring base):
Plugs and anchors can only ever support as much of a load as the anchoring base can handle.
REYHER fixing technology provides the proper technical and commercially economic solution from the catalogues of tried-and-tested proprietary brands FISCHER and UPAT for all intended uses.

The building material needs to be able to take the expansion force of the plug or anchor during frictional contact (➔ Section. 2) without suffering damage. (Approved plugs/anchors for the corresponding building material ➔ Table 6)

Table 1: Anchoring base acc. to building group

Concrete		Brickwork				Sheets/Panels
Normal concrete B 15 – B 55 C 15/20 – C 50/55	Light-weight concrete LB 10 – LB 55 e.g. Pumice/ expanded/porous (gas) concrete	**Solid brick dense structure** e.g. Solid brick (MZ)/ Sand lime solid bricks (KS)	**Perforated brick dense structure** e.g. Honeycomb brick Sand lime Perforated bricks (KSL)	**Solid brick porous structure** e.g. Porous concrete (G) Light-weight concrete (V)	**Perforated brick porous structure** e.g. Honeycomb brick Light-weight concrete Hbl	Plasterboard/ Chipboard/ Fibreboard/ Fibre cement panels
BN	**BL**	**VD**	**LD**	**VP**	**LP**	**HP**

2. Mode of operation (load anchoring in the building material)
Plugs and anchors are classified into three groups according to their force transmission in the anchoring base.
This type of carrier mechanism is also a decisive factor for the anchoring base, resilience, edge distances and centre distances.

Table 2: Types of force transmission from plugs and anchors in the building ground

Force transmission:	**Frictional contact** (Traction from expansion)	**Adhesive bond** (expansion free)	**Formschluss** (expansion free)
Support mechanism:	Contact pressure of the expansion parts on the wall of the drilling hole = Friction > Tensile loads 	Adhesive mortar joins with the anchor and anchoring base 	Plug shape/Anchor part shape adapts to the drill hole shape Plug/ Anchor types:	Plastic expansion plug Metal expansion anchor	Compound/Reaction anchor Injection anchor	Cavity plug Zykon anchor

3. The area of use (pressure zone or tension zone?)
When using heavy-duty plugs/anchors in concrete it is decisive to know if the anchoring is to be carried out in the area of a proven pressure zone (consistently non-cracked concrete) or in a tension zone by itself (cracking concrete/concrete inclined to crack).

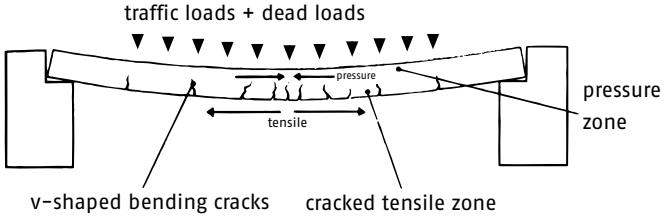
Tension zones with V-shaped bending cracks form in concrete due to its own weight, superficial loads, e.g. below ceilings. In this area of use, only plugs and anchors suited for crack/tension zones are permitted. Other plugs and anchors are only permitted for proved pressure zones.

(Tension-zone approved plugs and anchors ➔ Table 5)

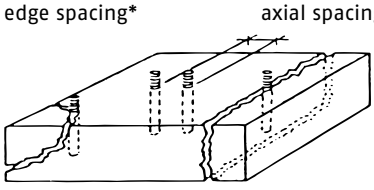
4. The anchoring position
Plugs and anchors with high expansion pressure and heavy loads can lead to cracks or concrete edge failure of the component in any anchoring base, especially with narrow/flat components.

According to their mode of operation, dimensions and load magnitudes, the plugs and anchors have been assigned the following to prevent
undesirable damage from happening:

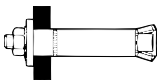
- Minimum component thicknesses
- Edge spacing
- Axial spacing (with plug pairs/groups)
- Minimum anchoring depths/installation lengths (➔ Section 7) in the relevant technical approvals (➔ Section. 9)



If in doubt, it is recommended to use tension zone approved plugs and anchors.



Non-binding typical values:
Edge spacing ≥ 2 x minimum anchoring depth
Axial spacing ≤ 4 x minimum anchoring depth
(the approval details are to be observed on a case-by-case basis)



5. Loading

Alongside the criteria treated in 1–4, the permitted load (F) per plug or anchor is influenced by:

a) Plug/Anchor dimensioning, installation depth, distances
b) Material/Property class of the plug/anchor and the building component into which the loads were inserted
c) Building component thickness, load working point, load type (pull, diagonal pull, pressure, transverse force, bending)
d) Safety factors, details in the approvals

For a) The basis used for the calculation is the size of the actually supporting threaded part (nominal size partially relate to the outer/sheath/drill diameters)

For b) The basis used for the values in approvals/from manufacturers apply to the corresponding form of delivery – e.g. steel, 8.8 or stainless steel A2/A4

6. Corrosion protection

The following guideline applies when specifying the proper protection of fixings against various types of corrosion:
The "Plug/Anchor fixing corrosion system" needs to be at least as fixed, durable and corrosion-resistant in the conditions of use as the parts to be fitted

The task of constructive planning is to determine the necessary corrosion protection measures:
Here the wear-and-tear contingency of the corrosion protection in known operating conditions is to be taken into account until maintenance is due or until the limitation of damages has been reached. Surface or material specifications are to be set accordingly in the article order text.

Table 3: Overview of the surface and material corrosion protection options

Delivery condition/ Corrosion protection	Extent of load/ Protective effect	Area of use	Notes
Zinc plated steel Coating thickness ~ 5–8 mm	I – II = mild – moderate	closed, dry interior rooms	
Hot dip galvanized steel (tZn) Coating thickness ≥ 40 mm	≧ IV = very strong	outdoor area e.g. pole/ crash barrier fixing	only with thicker dimensions due to the necessary play of the thread not a component of the tech. approval
Plastic (Nylon)	> IV = very durable	all atmospheric conditions	only special models on offer
Stainless steel A 4 (Werkst.1.4401/ 1.4571)	> IV = very durable	general atmospheric conditions rear-ventilated facades/roofs seawater/sea air	not for atmospheres containing chlorine (danger of pitting/stress corrosion)
Stainless steel Material 1.4529	> IV = very durable	specifically, indoor swimming pools, tunnels, parking garages, seawater areas	specifically for areas with high chlorine/chloride exposure

7. The clamp length – the installation length

The entire length of ready-to-install complete plugs/anchors for push-through installations is subdivided into:

- **Clamp length** ("use length", "grip strength", "grip thickness") $d_a/t_{fix}/d_p + t_{fix}$
  These need to be chosen as at least as large as the entire thickness of the assembly components to be fastened + non-structural construction material layers (plaster)
  – for stand-off fixing + distance
- **Installation length/Anchoring length h_{ef}**
  This needs to be integrated as a minimum anchoring depth in the fully load-bearing building material section. Load values only apply with the correct installation depth. See assembly instructions.

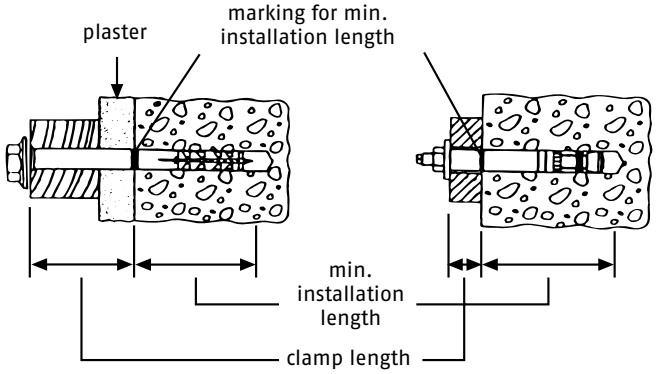
8. The assembly

Plugs and anchors can only achieve their intended task when they are properly installed.

The planner is to instruct the following for installation:
– Type, execution and dimension of the plug/anchor
– Edge and axial spacing on the component
– Special specifications of the technical approval

The grip/use lengths and the installation lengths/depths for the corresponding plugs and anchors are listed in the REYHER catalogue.

The following needs to be taken into consideration for correct assembly:
– The specifications of the planner according to sections 1 – 7
– Drills and drill techniques (➔ 8.1 Table 4)
– Drillhole ∅/depth (➔ Assembly instructions of the manufacturer)
– Borehole cleaning (➔ 8.2)
– Assembly type (➔ 8.3)
– Minimum anchoring depth/clamp length (➔ 7)



8.1 Drilling

Table 4:

Anchoring base		Drill	Drilling technique	Machine	Notes
Concrete	≧ B 25/C20/25	Hammer drills	Rotary/Hammer drilling low hammer count and high hammer power	Drilling hammer	for very large drillhole ∅ or very strong concrete reinforcement, if necessary diamond/core drilling method.
	B 15/C12/15	Stone drills	Impact drilling	Impact drilling machine	–
Solid building materials with dense/fixed structure		Stone drills Hammer drills	Impact drilling Rotary/Hammer drilling	Impact drilling machine Drilling hammer	depending on the component thickness and component stability
Light-weight building material with low strength (Porous/Light-weight concrete)		Stone drills	Rotary drilling without impact	Drilling machine	
			Impact drilling	Impact drilling machine	make sure that the drillhole does not get too large and that the bars of the hole/hollow brick stones don't break off
Perforated bricks		Stone drills	Rotary drilling without impact	Drilling machine	
Panels:	Plasterboard/ Fibre cement	Stone drills			
	Chipboard/ Wood/Wood-fibre boards	Spiral drill for wood			

8.2 Borehole cleaning

Since drill dust can not provide grip or can block the space of an undercut, all loose elements need to be removed from the drillhole before the plugs or anchors are inserted, e.g. by air-cleaning.

8.3 Assembly types (→ Figure 1)

8.3.1 The **push-through installation** is usually easiest for series assemblies and plug pairs as the insert holes of the building component can be used as drill gauges.

8.3.2 With **pre-positioned installation** the drillhole is to be accurately marked out. Internal thread anchors must end flush with the building material surface.

8.3.3 With **stand-off installation** pre-positioned inside thread/compound anchors with sufficiently long projecting lengths are to be used or fastening should be done with a suitably long screw.

8.4 Tightening torques/preloads

The values applicable for the various manufacturers and types are to be specified according to the technical approval by the construction engineer. Typical values can be found on the package or in the package insert.

8.5 Wrench sizes

For ready-to-install plugs and anchors, the wrench sizes are indicated on the package/in the package insert. The wrench sizes standardised for DIN/ISO screws apply to standard screws used for fastening, for example, inside thread anchors.

9. Approvals

For fasteners and anchors whose failure presents a danger to public safety, only plugs and anchors may be used which have been given approval for the use intended. General technical approvals are granted after type testing by the Deutsche Institut für Bautechnik (German Institute for Civil Engineering), Berlin (DIBT). Special approvals for particular uses are granted by the institutes declared responsible for them or the inspection centres of the relevant professional associations.
Plugs and anchors with CE logos require "European Technical Approval" (ETA).

Figure 1

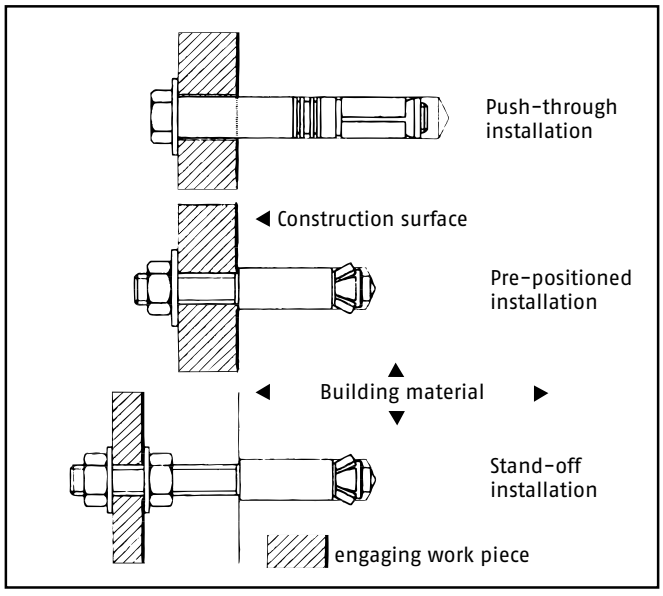


Table 5: Overview of the currently valid types of approval

European Approvals ETA CE	Building materials with the CE symbol may be traded freely in the EU economic zone. One of the requirements for the CE logo on plugs is the prior granting of European Technical Approval =ETA. ETA approvals are classified according to the use of the plug into options 1–6 for cracked concrete and 7–12 for non-cracked concrete. Approvals are granted based on • ETAG 001-1, -2, -3, -4 (future EAD 33-0232), • ETAG 001-5 (future EAD 33-0499), • ETAG 001-06 (future EAD 33-0747),

The "MULTI-MONTI® fastener system" is a fast, secure, time-saving and cost-cutting screw fastening method.

Without plugs and without expansion pressure, "MULTI-MONTI® screw anchors" can be mounted into building materials like
- Concrete, natural stone
- Lime sand brick
- Solid brick, clinker brick
- Hollow-block concrete

"MULTI-MONTI® screw anchors MMS-plus are well-suited to all regular standard fastenings.

Standards and standard conversion for blind rivets

For the use of blind rivets as calculable construction elements, it was necessary to normatively and uniformly regulate dimensions, mechanical properties, such as tension and shearing loads, as well as general quality-related requirements.

This was done in the national standard DIN 7337 "Blind rivets with break pull mandrel" - first publication May 1985 - amended version July 1985 - follow-up version August 1991.

DIN 7337 – August 1991 included the version: Type A protruding head and type B countersunk head. In May 1997, the version "Open rivets with break pull mandrel" included published as the intended follow-up version for DIN 7337 – August 1991 with additional type C large protruding head.

In 1997, the international and European standards, ISO and EN, adopted the standardisation of the blind rivets.

Then, the basic standards, ISO 14588 and 14589, were published in August 2001.

In April 2003, the product standards, ISO 15973-16585 followed – a separate standard for each material combination/version/type. Here, DIN 7337 incl. design were withdrawn.

For the standardised versions and higher, special types are offered for particular uses.

For the conversion to ISO standards, production needs a certain amount of customisation/transition time. Until otherwise regulated, the article descriptions and REYHER article numbers in the article heads of this catalogue apply to the blind rivets offered. The Technical Information in the TI section of this catalogue also applies here.
For versions and/or material combinations for which standards currently do not exist, subsequent ISO standardisation or a remaining standard, DIN 7337, may have to be reckoned with.

AlA = aluminium alloy (Al alloy) – SSt = stainless steel
St. = steel (should be protected for storage – e.g. zinc plated version)

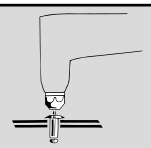
Blind rivets: Function and assembly process

Blind rivet technology was developed as a fastening procedure for hollow profiles and similar single-side access use fields.

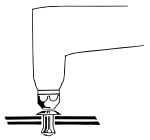
The simple, fast, and thus very economical, blind rivet principle has since replaced conventional fastening tasks in many assembly fields and is continually finding new fields of application.

REYHER has a comprehensive range of blind rivets so that a suitable design is available for every purpose.

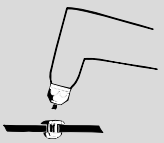
The placement devices provided are ergonomically formed and designed for long-term professional use.



The blind rivet is inserted into the drill hole from the front of the work piece. The drift pin is incorporated until the head fit from the die of the setting tool. The blind rivet size is based on load and material strength.



Through operation of the setting tool the protruding end of the rivet body is reformed through the drift pin head into a closing-head.
At the same time the materials are compressed.



c the rivet pin is pre-programmed to snap off at the predetermined breaking point – a secure rivet fastening is completed.

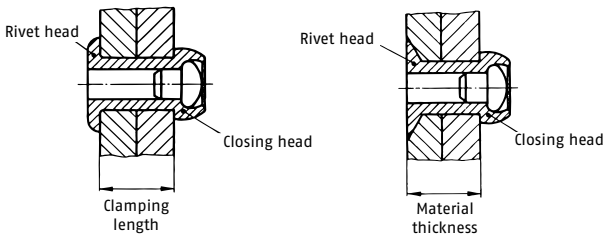
Rivet length specification:

For blind rivets with smooth rivet shafts and head types A, B, C or similar, the suitable nominal length can be set according to the rule of thumb:

Clamping length (material thickness) + 1 x rivet nom. Ø = rivet nominal length min.*

(*for interim results, the next-largest rivet length is to be chosen)

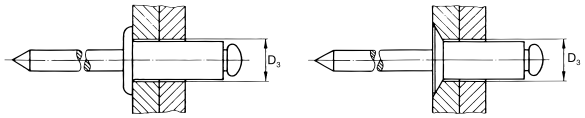
The allocation of the rivet nominal length according to clamping length/ material thickness differs minimally for standard blind rivets – between standard specifications (DIN 7337, attachment A and B) and factory specifications – according to various material combinations.



Rivet hole/Drill diameter:

For blind rivets of the types A, B or C corresponding or similar to DIN 7337 as well as for "CAP" and "PolyGrip" multi-section blind rivets, the rivet/ drill hole diameter is specified according to the following rule of thumb:

Rivet nom. Ø: d1 + 0.1 mm (tol. +0.1 mm) = Rivet hole/Drill hole Ø D3



The following applies for blind-rivet nuts:
Shaft Ø: d1/wrench size + 0.1 mm = Drill/Punch/Hole Ø D3

Blind rivet nuts: Function and assembly process

By combining two fastening options, blind rivet nuts provide cost and quality benefits. On the one hand, a rivet fastening is made by rivetting the nuts with sheet metal and, on the other hand, a screw fastening is created. This combination makes it possible to use thin-walled component parts for which the inclusion of a thread is sometimes problematic due to the low material strength. A further advantage is that a detachable screw fastening is created without any heat impact and thus, an unchecked thermal lag in the components can be prevented. Additionally, various materials can be connected with each other.

			The blind rivet nut is screwed onto the thread mandrel and inserted into the drill hole from the front side of the workpiece. The length of the blind rivet nut is based on the material strength.
		b	By using the setting tool the blind rivet nut is reshaped, which creates a firmly-sitting, immovable thread in seconds. At the same time, materials can be pressed together in this process.
		c	After unscrewing the thread mandrel, a metric screw can be used to fasten an additional part.

The following table shows the minimum thread breaking force and guide values for a tightening torque.
The thread breaking force is determined under axial tensile load in the smallest and largest clamping range of the blind rivet nut.
The tightening torque is tested with a grease-free screw of property class 10.9 and a hardened washer as a clamping part.

Table 1: Minimum thread breaking force and guide values for tightening torques

Thread nominal -Ø	Material	Blind rivet nuts round		Closed blind rivet nuts		Multi-range blind rivet nuts		Blind rivet nuts with hexagon	
		Thread breaking force [N]	Tightening torque [Nm]	Thread breaking force [N]	Tightening torque [Nm]	Thread breaking force [N]	Tightening torque [Nm]	Thread breaking force [N]	Tightening torque [Nm]

Dimension, form and position tolerances for washers are determined in theISO 4759-3.

For dimensions without tolerance specification applies ISO 2768 (DIN 7168) m for product class A and ISO 2768 (DIN 7168) g for product class C.

The washers shown are only examples. The information also applies for other standard and non-standard washers.

In the following tables, only the information for the standard product classes A and C.

The reference measure is the information specified in the respective product standards individual measure.

Excerpts from ISO 286, 965, 4759 (DIN 267-2, 7160, 7161, 7168)

Technically a thread is "a bevelled level equally wound around a cylinder".

This principle enables both a screw on/in as well as screw off function and thus forms the basic characteristic for "detachable" fastenings = screws and nuts.

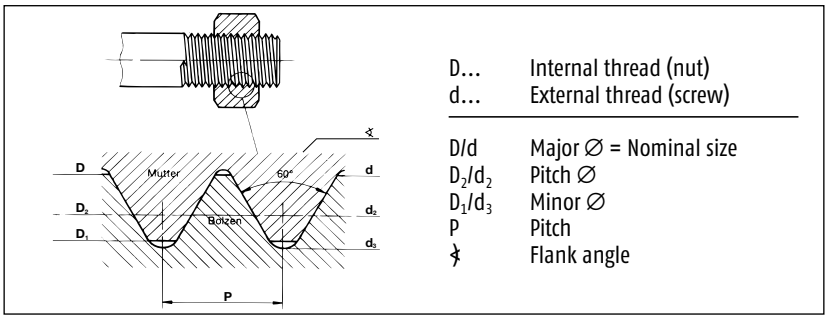
The geometric shape and the standardised dimension and tolerance system are the requirements for the coupling and exchangeability of the same kinds of thread profiles.

Thread profile, thread measuring points

The basic profile and the five measuring points of the thread are illustrated in figure A.

For external threads (screw) the dimension inspection is executed using ring gauges, flank micrometers and optical measuring devices, for internal threads (nuts), this is done using plug gauges.

Figure A:
Thread profile with 5 measuring points



Thread types

Table 1 shows an overview of the most common thread types for screws and nuts. The metric ISO thread has been valid since 1963 as a basis for global, uniform standardisation (ISO) for "Mechanical Fasteners".

Table 1: Overview of the most conventional thread types for mechanical fasteners (excerpt from DIN 202)

Thread manufacture

- Non-cutting production
  (= normal for large series production of screws)
  – thread rolling using profile barrels (M 2–M 30)
  – thread rolling using profile rolls ≥ M 20
- Metal-cutting production
  – cutting using profile threading die
  – thread-chasing using profile clip
  – reeling using profile threading die
  – milling, grinding (for special movement threads)

Fit of thread/threadability

For the screw-in function of internal and external threads (e.g. screw with nut), the standards are generally based on the functional quality upon assembly with the corresponding tool.

With additional thicker layers/coatings and/or required light-running clearance in the thread (manual assembly) additional measures and order information are necessary!

The basic parameters for threadability:

- **placement of tolerance**
  = Distance of the upper dimension of the external thread to the lower limit deviation of the internal thread
  ➔ Figure B
- **tolerance interval**
  („Tolerance quality")
  = Distance of lower to upper limit deviation
  (interval size es–ei/EI–ES)
- **length of thread engagement:**
  Minor form and position differences which can occur depending on the length as a kind of lead deviation are unavoidable in mass production.

  For this reason, length of thread engagement of the external thread into the internal thread for normal screw fastenings (= screw-in group N) according to ISO 965/DIN 13-14 is restricted due to pitch dependency.
  ➔ Table 3

  For higher lengths of thread engagements (L) correspondingly larger tolerance intervals are to be selected.

- **Surface discontinuities/damages to the thread**
  During thread production, small laps and/or profile deviations may occur – in the later manufacturing process (quenching and tempering, transport, drum-coating) minor damage like dents, nicks and gouges are unavoidable and make the threadability with thread gauges and mating threads more difficult.

  These manufacturing-related surface discontinuities/damages are permitted up to specific limits according to ISO 6157-1/-3 (DIN 267-19) for screws or according to ISO 6157-2 (DIN 267-20) for nuts.

  Should especially smooth-running threads be necessary for specific operating situations, either higher tolerance qualities or supplementary "smoothing rolls" with thread protection are needed.

Note: The standardised permitted stress loads for screw fastenings are valid for the tolerances assigned in the respective product standards. Understandably, increases in the tolerance placements/intervals lead to a reduction in the stress capacity in the thread.

Figure B: Placement of tolerance tolerance interval

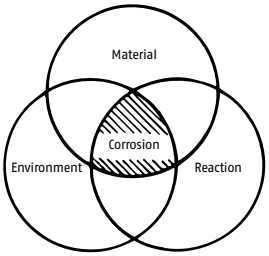
General information



Corrosion is the reaction of a metallic material with its environment which causes a measurable change in the material and can negatively influence the function of a metallic component or an entire system. In most cases, this reaction is of an electrochemical nature, but, in some cases, it can be of a chemical or a metal-physical nature. (Definition: Basic principle of "Corrosion" according to ISO 8044)

Table 1 shows the most important corrosion types from a selection of different corrosions which need to be considered with "mechanical fasteners".

Table 1: Corrosion types

				Surface corrosion, e.g. rust, pitting corrosion	Crevice corrosion	Electrochemical corrosion (Contact corrosion) (see Table 2)	intergranular/ transgranular corrosion	Stress corrosion cracking

Corrosion is unavoidable, but damage due to corrosion is avoidable, provided the proper planning of suitable corrosion protection measures is in place. The corrosion protection of screw fastenings needs to be at least as corrosion-resistant as the components to be connected.

The task of constructive planning is to determine the necessary corrosion protection measures. Here the resilience of the corrosion protection in known operating conditions is to be taken into account until maintenance is due or until the limitation of damages has been reached. Surface or material specifications are to be listed in the article order text according to standards.

The next page provides a rough overview of the corrosion protection options for fasteners.

Inspection standards for corrosion protection procedures, compiled in DIN pocketbook 175, stipulate uniform conditions for the type and setup of equipment and methods for checking adherence to the specified coating type, layer thickness and optical appearance. The inspections according to these standards do not provide any information on the effect or fatigue strength of the corrosion protection under practical operating conditions.

An overview of the friction coefficients for various surface combinations → TI assembly. The friction ratios in the screw fastenings are vital when determining the correct tightening torque (→ VDI 2230)

Electrochemical corrosion

The combination of electrochemical noble and ignoble metals in humid conditions (= electrolyte) generates corrosion currents which spread from ignoble (anodic) metal to more noble metal (cathode). This means that less noble metal will be more eroded or corroded. The corrosion current thicknesses are also vital. If the ignoble, anodic part is small in comparison with the surrounding cathodic area (screw head on sheet surface), a very high anodic current thickness will generate which will carry off a lot of material.

Example 1:
Zinc plated screws for fastening a copper sheet:
Zinc is considerably less noble compared to copper. In humid conditions, a very high corrosion current thickness occurs on the small, ignoble, anodic screw head (left column zinc – small) in the direction of the noble, cathodic copper sheet (upper row – copper). The galvanized surface of the screw erodes in a short space of time and red rust appears on the steel.

Remedy:
In relation to the metallic building component, the fasteners should be as similar as possible if not more noble.

Screw	Component
zinc plated	zinc plated
nickel plated	steel, copper, brass
stainless	steel, zinc plated, aluminium, copper, brass

Example 2:
Copper or stainless steel screws which work in a similar way for fastening a zinc plated metal sheet:
This time, the ignoble, anodal, galvanized section is very large in relation to the small, noble, cathodic screw head. The corrosion current which stretches over the entire surface has very low tightness in the anode. The material degradation occurs across the entire surface and shows hardly any corrosion. This process actually additionally protects the nobler screw head against corrosion.

If unfavourable metal pairings cannot be avoided, they should be isolated from each other, e.g. using intermediate layers or coatings. Here, it must be made sure that the full strength of the connection remains intact.

Table 2: Electrochemical corrosion with metal pairings

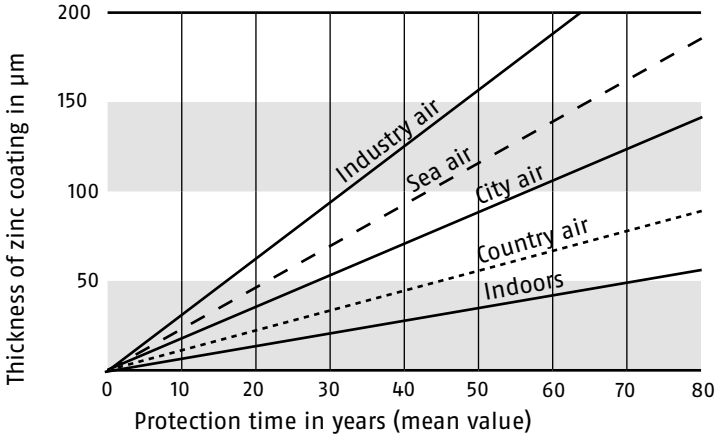
Service conditions for zinc plated steel

	Service condition	Duration of salt spray test without base metal corrosion (NSS) in hours
0	Decorative use (without strain)	48
1	Indoor conditions in warm, dry atmosphere	72
2	Indoor condition in rooms, in which condensation may occur	120
3	Outdoor weathering under moderate conditions	192
4	Outdoor weathering under difficult corrosive conditions – e.g. salt/industry environment	360

- Extract from ISO 2081:2009-05, EN 1403
- The listed protective effects vary in practice and are mere reference values
- Suitable coatings are listed below

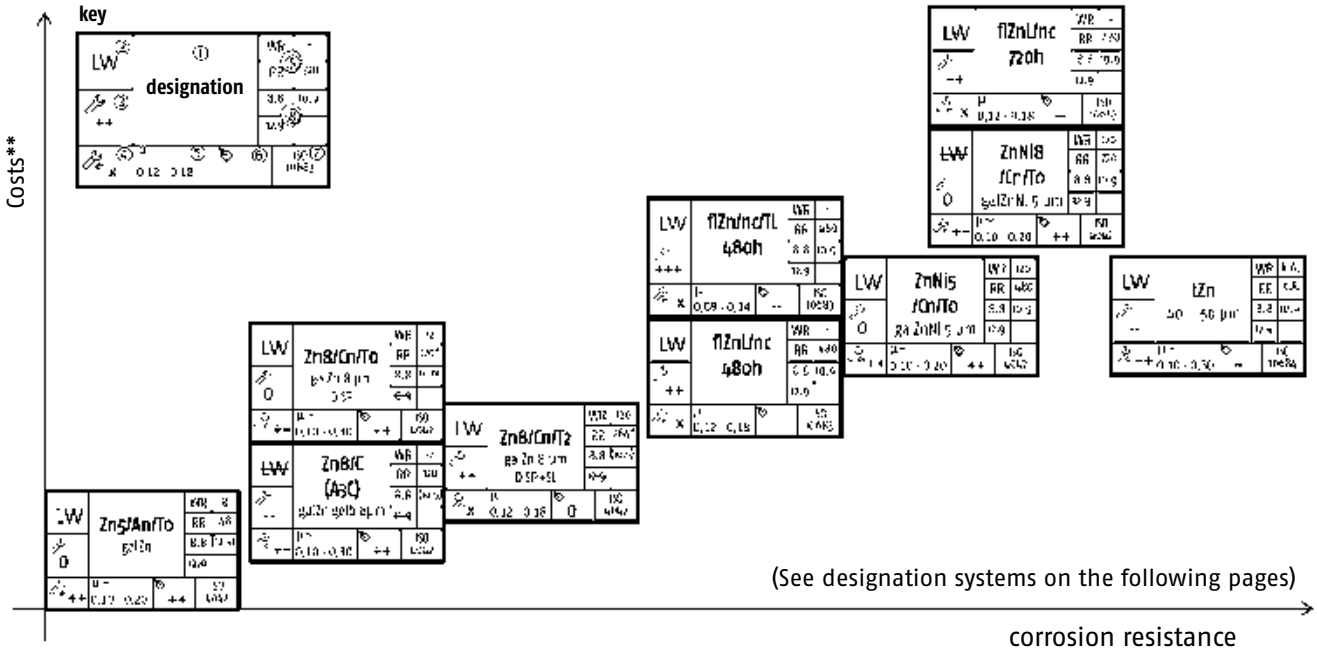
Table 7:
Yearly erosion values for zinc



Service condition	µm/year
Indoors	1.0 – 2.0
Country air*	1.3 – 2.5
City air*	1.9 – 5.6
Industry air*	6.4 – 19
Sea air*	2.2 – 7.2

*In practice, a mixed climate is to be reckoned with.

Overview of common coating systems



1) Designation of surface; 2) Products with this surface in stock; 3) assembly behaviour (friction coefficient spread) without additional lubrication (-- = bad to ++ = very good); 4) assembly behaviour (friction coefficient spread) with additional lubrication (-- = bad to ++ = very good / x = lubrication already contained in surface); 5) friction coefficient range in delivery condition (µ~ = typical values) 6) Bonding suitability of surface (-- = bad to ++ = good); 7) Standard for technical delivery conditions; 8) Suitability of surface for property classes; 9) corrosion resistance in salt spray test (WR = white rust; RR = red rust)

*Deviating from ISO 4042
**the categorization gives an approximate, nonbinding overview of costs

Corrosion protection: Electroplated coatings

The technical conditions of delivery ISO 4042 apply to electroplated coatings on standard and non-standard fasteners.
The coating metal is applied onto the parts to be coated in an electrolytic precipitation process in an electroplating bath.

Layer composition and description system of electroplated coatings

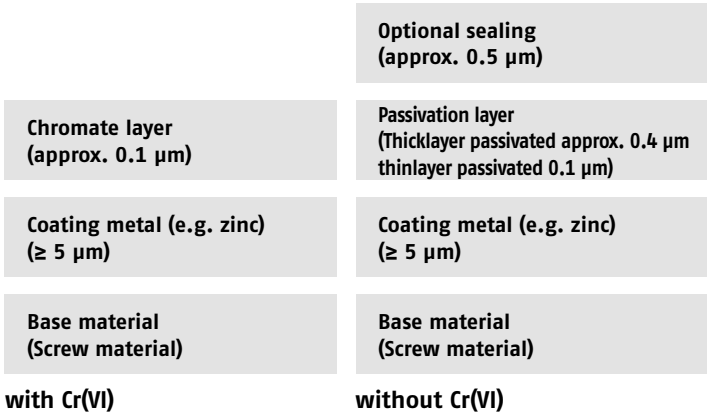


Table 8: Coating metals (Extract from ISO 4042)

Symbol	Description	Type
Zn	Zinc	Metal
ZnNi	Zinc-nickel	Alloy
ZnFe	Zinc-iron	Alloy
Ni	Nickel	Metal
Ni+Cr	Nickel-Chrome	Multi-layer
Cu+Ni	Copper-Nickel	Multi-layer
Cu+Ni+Cr	Copper-Nickel-Chrome	Multi-layer
CuZn	Brass	Alloy
CuSn	Copper-Tin (Bronze)	Alloy
Cu	Copper	Metal
Sn	Tin	Metal

Table 9: Sealings/topcoats/lubricants

Code	Description	Requirement
–		Manufacturer's choice
T0	No sealing or topcoat	To achieve a certain function, no sealing or topcoat shall be applied
T2	Sealing	Sealing to increase corrosion resistance with or without integrated lubricant
T4	Subsequently applied lubricant	A lubricant shall be applied to the metal coating or the conversion layer or the sealing/topcoat
T7	Topcoat	e.g. increase chemical resistance or colouring scheme
nL	No lubricant	There shall be no integrated lubricant in T2 or T7

Table 10: Conversion layers for zinc and zinc alloy coatings

Code	Name	Typical look	Type of conversion layer
An	Transparent	Transparent, clear to bluish	Passivation without Cr(VI)
Cn	Iridescent (Thick layer passivation)	Transparent, clear to iridescent	Passivation without Cr(VI)
Fn	Black	Black, dark iridescent permitted	Passivation without Cr(VI)
A	Clear	Transparent, clear to bluish	Chromation with Cr(VI)
C	Iridescent	Yellow iridescent	Chromation with Cr(VI)
D	Matt	Olive	Chromation with Cr(VI)
F	Black	Black, dark iridescent permitted	Chromation with Cr(VI)
U	–	No conversion layer	–

1) in drum-coating; inspection is performed directly after coating				

Note: These are only extracts from standards. For inspection purposes, please refer to the relevant standard.

Requirements for gaugeability and assemblability of fasteners as per ISO 4042

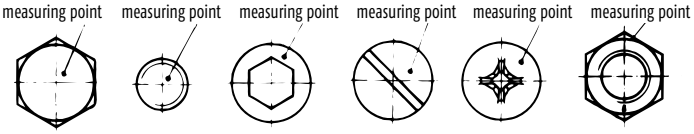
The tread tolerances apply before the coatings are plated – when coating, the zero line of a screw thread (tolerance range h) or nut thread (tolerance range H) shall not be exceeded and deceeded, respectively. Thus, the screw thread with coating may be in between the upper tolerance limit and the zero line. The threads shall be gaugable over the complete thread length. Deviating from this, the threads may be damaged in delivery condition due to transport and pouring processes. In this case the maximum torques of a thread gauge shall not exceed the value of $0.001 d_3$ in Nm (Table 13). Alternatively, order and supplier may agree on an inspection for assemblability with a suitable nut or screw.

In the interest of threadability, the layer thickness for thread parts with a normal degree of tolerance of 6g/6H is of course limited. The empirically recommended limit values possible according to ISO 4042 can be found in Table 14. Thicker coatings require different tolerance zones with larger sizes according to DIN 13-14 (custom-made).

Layer thickness inspection of electroplated coatings on fasteners

In order to determine the layer thickness, different testing methods can be applied (X-ray spectrometric method as per ISO 3497, coulometric method as per ISO 2177, microscopical method as per ISO 1463, magnetic method as per ISO 1463, or eddy current method as per ISO 21968). In case of arbitration, the microscopical method shall be applied.

The test shall be performed at the reference areas marked in the figure.



Normal storage:	Layer thickness = Type (≥ M 5)
"galZn"	approx. 5 µm
"galZnC" yellow chromate	approx. 5 µm
"galZn 8 DiSP"	approx. 8 µm thick layer passivation

Table 13: Maximum torque for gauging of coated metric threads as per ISO 4042

Notes on manufacturing-related hydrogen embrittlement (ISO 4042)

The risk of manufacturing-related hydrogen embrittlement exists (IHE = internal hydrogen embrittlement), if the fastener has high hardness or tensile strength, is subjected to tensile stress and can absorb atomic hydrogen during the manufacturing process.

Table 15: Measures to reduce hydrogen embrittlement with regard to hardness as per ISO 4042

Measure	A	B	C[a]
Description measure	No supplementary process verification or product testing with regard to IHE AND No malleablizing required	Supplementary process verification and/or product testing with regard to IHE OR Malleablizing	Supplementary process verification and/or product testing with regard to IHE AND Malleablizing
Applicable for screws of property class as per ISO 898-1	≤ 8.8	10.9	12.9
Applicable for nuts of property class and hardness as per ISO 898-2	≤ property class 12 and < 360 HV	≤ property class 12 and < 360 HV	-
Applicable for washers of property class as per ISO 898-3	≤ 200 HV	300 HV	380 HV

[a] As, despite measure C the risk of hydrogen embrittlement cannot be ruled out completely for the listed screws and washers, they are manufactured only upon explicit order.

Corrosion protection: Zinc flake coatings

The technical conditions of delivery ISO 10683 apply to non-electrolytically applied zinc flake coating on standard and non-standard fasteners. The coating is composed of zinc and aluminium flakes linked by an inorganic matrix. It is applied onto the part surface in a dipping or spraying process and then burned in at temperatures between 200 ° - 320 °C.

Layer composition and description system of zinc flake coatings

Variations in layer composition:

- Basecoat only
- Basecoat + lubricant
- Basecoat + topcoat
- Basecoat + topcoat + lubricant

Optional - lubricant

Optional topcoat optional with integrated lubricant (topcoat)

Basecoat optional with integrated lubricant (basecoat)

Base metal

Table 16: Comparison of resistance in the salt spray test to reference layer thickness according to ISO 10683

Duration NSS without red rust [h]	Reference layer thickness a) [µm]
240	4
480	5
600	6
720	8
960	10

a) The reference layer thickness includes basecoat layer(s) and topcoat layer(s), if present, with or without cr(VI). For approval, the corrosion resistance is decisive; the indication of the reference layer thickness is merely for orientation.

Table 17: Designation system according to ISO 10683

Basecoat	Chromium(VI)	Topcoat	Additional lubricant	Duration of salt spray test until red rust	Requirements for the friction coefficient range
1. Without integrated lubricant = **flZn**	1. Not specified (manufacturer's choice)	1. With integrated lubricant in the top layer = **TL**	**L**	e.g. **480 h**	**C**[a]
2.With integrated lubricant = **flZnL**	2.With Cr(VI) = **yc**	2.Without integrated lubricant in the top layer = **Tn**			
	3. Without Cr(VI) = 3: **nc**				

a) Friction coefficient range µ must be named in the order

Description example for a screw with zinc flake coating as per ISO 10683
ISO 4014 – M 16 x 60 – 8.8 flZnL/nc/480h/C (µ = 0.12–0.18)

flZnL	nc	480h	C (µ=0.12-0.18)
			Requirement for a friction coefficient range µ between 0.12 and 0.18
		Corrosion resistance in salt spray test 480 h to red rust

NOF	Basecoat: Topcoat:	GEOMET PLUS L ® PLUS VL ®

Requirements for gaugeability and assemblability of fasteners as per ISO 10683

The thread tolerances apply before the coatings are plated – when coating, the zero line of a screw thread (tolerance range h) or nut thread (tolerance range H) shall not be exceeded and deceeded, respectively. Thus, the screw thread with coating may be in between the upper tolerance limit and the zero line. Threads may be damaged in delivery condition due to transport and pouring processes. In this case, the maximum torques of a thread gauge shall not exceed the value of 0.001d3 in Nm (Table 19). Alternatively, order and supplier may agree on an inspection for assemblability with a suitable nut or screw.

Table 19: Maximum torque for gauging of coated metric threads per ISO 10683

Thread	Max. Torque [Nm]	Thread	Max. Torque [Nm]
M 3	0.03	M 18	5.8
M 4	0.06	M 20	8
M 5	0.13	M 22	11
M 6	0.22	M 24	14
M 8	0.51	M 27	20
M 10	1	M 30	27
M 12	1.7	M 33	36
M 14	2.7	M 36	47
M 16	4.1	M 39	59

Properties of zinc flake technology at a glance:

- No hydrogen embrittlement as a result of the application process
- Virtually all systems are now Cr(VI)-free in accordance with according to RoHS and EU-End-of-Life-Vehicles Directives
- Extremely thin coatings of typically 5 - 12 µm
- Caution, however, with cropped parts with internal drive and small diameters ≤ M 6
- High cathodic corrosion protection compared to electroplated standard surfaces

Note: These are only extracts from standards. For inspection purposes, please refer to the relevant standard.

Corrosion protection: Hot dip galvanized fasteners

For hot dip fasteners, the technical conditions of delivery apply according to ISO 10684.

Requirements for thread and geometry tolerances

The minimum layer thickness of at least 40 µm at the point of measurement stipulated by this standard requires that the thread dimensions be adjusted (see Table 10).

The undersize is usually to be found in the screw thread with the tolerance group 6az so that the hot dip galvanized screw thread does not exceed the (ISO-compatible) zero line (h tolerance). These screws are also identified with a "U".
Rethreading the screw is not permitted.

For high-strength structural bolting assemblies -system HV- according to EN 14399-4, a non-rethreaded screw (g tolerance) is coated which means that the screw thread with hot dip galvanization is above the zero line. In this case the necessary oversize is in the nut thread (= 6 az).
The nut thread is later cut into the hot dip galvanized castings. The corrosion protection of the bare nut thread comes from the zinc coating of the screw thread with remote cathodic protection.

In case of external dimensions (head, shaft), there may be a minor oversize due to the zinc layer.

Table 20: Basic dimensions of the screw thread before hot dip galvanization – tolerance group 6az according to ISO 10684/ISO 965-4

Coarse thread	M 6*	M 8	M 10	M 12	M 14 M 16	M 18 M 22	M 24 M 27	M 30 M 33	M 36 M 39	M 42 M 45	M 48 M 52	M 56 M 60	M 64

*not regulated by standards

Requirements for mechanical properties

After hot dip galvanization, the requirements of ISO 898-1 and ISO 898-2 apply to hot dip galvanized screws and nuts ≥ M 12.
For thread sizes M 8 and M 10, reduced load bearing capacities apply according to ISO 10684.

Table 21:

Assembly

When assembling hot dip galvanized screws and nuts, especially with additional lubrication of the threading, different friction coefficients and tightening torques need to be reckoned with. EN 1993 – 1 – 8 NA needs to be considered for hot dip galvanized high strength structural bolting assemblies!
(→TI - Assembly)

Requirements for coating and surface

The grey appearance of the hot dip galvanized surface is dependent on the material and not a characteristic for the quality of corrosion protection. White rust and/or whitish to dark corrosion points (zinc oxide), which may occur after hot dip galvanization, e.g. through dampness, do not usually impair the corrosion protection and are no reason for rejection (→ ISO 1461, section 6.1).

A certain surface rawness and small dents in the thread tips are dependent on the procedure. For this reason, an assembly tool may be required for initial screwing.

Suitability of hot dip galvanizing for fasteners

Due to the great layer thicknesses and the coating process, coating is standardized only for thread diameters starting from M 8. Fasteners with a diameter of M 6 are suitable for hot dip galvanizing to a limited extent.

Articles with hollow sections (e.g. cap nuts, hexagon socket screws) are not suitable for hot dip galvanizing.

Properties: Steel screws, bolts and studs with metric thread

The mechanical properties of steel metric screws as well as their quality inspection and marking are set in ISO 898-1.
For fasteners under compressive stress with external thread, such as e.g. studs, only hardness classes are defined acc. to ISO 898-5.

Designation system for property classes
The most important mechanical properties for steel screws are given a two-digit combination name – here's an example:

The first number gives 1/100 of the **minimum tensile strength** in N/mm² stress area.
Tensile strength 8 x 100 = 800 N/mm².

← **8.8** →

The second number specifies the 10-fold ratio of the lower yield strength limit (R_{el} or Rp 0.2) over nominal tensile strength R_m (yield strength ratio).
Multiplying the two numbers results in 1/10 of the **minimum yield strength** in N/mm².
Tensile strength 8 x 10 = 640 N/mm².

Table 1: Mechanical properties of screws, bolts and studs as per ISO 898-1

Properties	Property classes	3.6	4.6	4.8	5.6	5.8	6.8	8.8 ≤ M 16	8.8 >M 16*	10.9	12.9

Marking screws, bolts and studs
According to the standard, fasteners from a thread diameter of M 5 onward are to be marked with the manufacturer's identification marks and the property class marking as follows*:

Hexagon and hexalobular head screws and bolts in all property classes. The marking shall be made preferably on the top of the head by indenting or embossing.

Hexagon and hexalobular socket head cap screws in all property classes. The marking shall be made preferably on the top of the head by indenting or embossing.

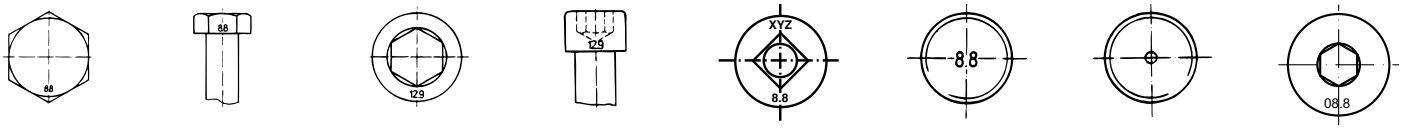
Cup head square neck bolts in all property classes. The marking shall be made on the head by indenting or embossing.

Studs 5.6 and starting from property class 8.8. The marking shall be on the unthreaded part of the stud or on the tip of the nut end. If this is not possible, marking symbols an be used as follows: 5.6 = –, 8.8 = p, for 10.9 = l and for 12.9 = g

Threaded rods acc. to DIN 976 (DIN 975) are marked with the property class starting from 5.6. The manufacturer's identification is not required.
Alternatively, the following colour marking is allowed:

Property class/ material	Colour
5.6	brown
5.8	blue
8.8	yellow
10.9	white
12.9	black
A2-70	green
A4-70	red

Marking of fasteners which have reduced loadability, such as, hexagon socket head cap screws with low head for example (DIN 7984): Fasteners shall be marked with the property class, except that the marking symbol for property class shall be preceded by the digit "0" (e.g. "08.8"). The obligation to add a marking is regulated in the product standards. Other screws with reduced loadability are, for example, hexagon socket countersunk head screws acc. to ISO 10642.



*According to ISO 898-1, in case of limited space marking can be made clockwise (➔ analogue table 3)

Table 2: Hardness classes for set screws per ISO 898-5

Designation	14 H	22 H	33 H	45 H
Vickers hardness HV min.	140	220	330	450

Marking of products is not mandatory or only regulated in the product standards.

Properties: Steel nuts with metric thread

The DIN product and function standards for nuts are being converted to ISO standards. Accordingly, during the transition period standards for previous DIN and new ISO nut designs shall be on the market together.

Information about standards conversion, "Standards conversion DIN ➔ ISO", see TI-7:

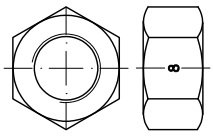
The properties of nuts with coarse threads is specified in ISO 898-2 (EN 20898-2/DIN 267-4) and for nuts with fine threads in ISO 898-6. The loadability of a nut is set by the hardness & nut height and defined by the proof load.
It is regulated that specific nut types must be marked with the property class.
The type of marking as well as the place where it needs to appear is prescribed in the standards ISO 898-2, DIN 267-24 and DIN 267-13, among others.
The key number specifies a direct assignment of property classes of the screws, bolts and studs (➔ Table 2).

Nuts with nominal height ≥ 0.8 D

The first number of the property class of the screw/bolt/stud is the assignment of the property class of the nut. For nuts with a nominal height of ~0.8 D, e.g. nuts according to DIN 555 and DIN 934, the marking is a number, for instance (8 = 1/100 of the proof stress in N/mm²). The marking of two vertical bars (| |) refers to the applicable proof loads according to DIN 267-4.

For nuts with a nominal height of ≥ 0.8 D, e.g. nuts according to ISO 4032, ISO 8673, the marking is a number, for instance (8 = 1/100 of the proof stress in N/mm²), without marking of two vertical bars (| |), here the proof loads apply according to ISO 898-2.

Marking: Hexagon head nuts of this group are to be marked from a thread diameter of ≥ M 5 with the manufacturer's identification mark and the property class in accordance with Table 2 or Table 3.



8
8

Table 3: Assignment of the nut property classes to the screw property classes

Property class of the nut	Associated screw/bolt/stud		Nut - Thread range	
	Property class	Thread range	Type 1[1)]	Type 2[1)]
4	4.6 4.8	> M 16	> M 16	
5	4.6 4.8 5.6 5.8	≤ M 16 ≤ M 39	≤ M 39	
6	6.8	≤ M 39	≤ M 39	
8	8.8	≤ M 39	≤ M 39	> M 16 ≤ M 39
10	10.9	≤ M 39	≤ M 39	
12	12.9	≤ M 39	≤ M 16	≤ M 39

1) The type determines the necessary proof loads in ISO 898-2.

Note in accordance with ISO 898-2: In general, nuts from the higher property class can be used instead of nuts from the lower property class. This is recommended for a screw-nut fastening with loads above the yield stress or above the proof stress.

Table 4: Alternative marking of the property class with symbols (clock system)

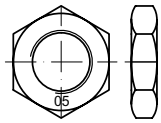
Property class	4	5	6	8	10	12 [2)]
Marking						

2) The marking placement cannot be replaced by the manufacturer's identification mark

Nuts with nominal height ≥ 0.5 D < 0.8 D

For nuts with a nominal height of ≥ 0.5 D < 0.8 D, e.g. nuts according to ISO 4035, ISO 8675 and DIN 439-2 the marking is a number prefixed with "0", e.g. (05 = 1/100 of the proof stress in N/mm²).
The prefixed 0 shows that nuts from this group cannot or can only limitedly take on the loads of a screw due to the low nut height.

Marking: Hexagon head nuts of this group are to be marked from a thread diameter of ≥ M 5 with the manufacturer's identification mark and the property class.



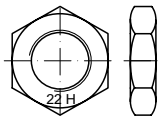
05

Nuts with nominal height < 0.5 D

For nuts with nominal height < 0.5 D, for example, nuts according to DIN 936, there is a marking of 1/10 of the minimum hardness according to Vickers, e.g. 22 H (= 220 HV).

Nuts for easy fastenings without specified proof load values are included in this group.
The hardness classes for these nuts are specified in DIN 267-24.

Marking: Nuts of the hardness class 22 H are to be marked with a hardness class if the thread diameter ≥ M 5.



22 H

Properties for fasteners made of steel with inch thread as per ASME standards

The properties of fasteners as per American ASME standards are regulated in the following standards among others:

- Hexagon head and square head screws: ASME B18.2.1-2010
- Hexagon socket head cap screws: ASME B18.3-2012
- Nuts: ASME B18.2.2-2010
- Plain washers: ASME B18.22.1-1965

The property classes/mechanical properties for these fasteners are regulated in different norms and standards that are partly included in the product standards. A clear and strict separation as in the field of DIN/EN/ISO standards in product and function standards is not present in the field of ASME standards.

Properties of hexagon head screws as per ASME B18.2.1-2010 Table 6

The ASME B18.2.1-2010 standard regulates the properties of hexagon head and square head screws with inch thread. The standard specifies 8 different product geometries here. An important difference is the difference between so-called "bolts" and "screws". Unfortunately there is no generally valid definition of "bolts" and "screws". In the area of hexagon head screws, "bolts" are always screws without a pronounced washer face; in contrast "screws" always have a washer face. The properties of hex cap screws (ASME B18.2.1-2010 Table 6) are dealt with in more detail in the following. There is no difference between partial and full thread in this standard; screws up to a specific length are supplied with full thread, longer products with partial thread.

Table 5: Overview of full thread/partial thread as per ASME B18.2.1-2010

Diameter in inches	Dimensions with full thread (R 83933)	Dimensions with partial thread (R 83931)	Minimum and maximum length of partial thread in inch	
	Length to in inch	Length from to in inch	min.	max,
1/2	1 1/8	1 1/4 to 6	3/4	1,000
5/16	1 1/4	1 5/16 to 6	7/8	1,153

2 3/4	7 5/8	7 3/4 to 12	5 3/4	7,000
3	8 1/8	8 1/4 to 12	6 1/2	7,500

REYHER nevertheless offers a separation here, item 83931 corresponds to the longer dimensions with partial thread and item 83933 corresponds to the shorter dimensions with full thread.

The thread tolerances for inch screws are regulated in the ASME B18.1.1 standard where the following tolerances apply:

- Tolerance limit 2A prior to galvanic coating,
- Tolerance limit 3A (go-master ring) and 2A (no-go gauge) after the coating

unless otherwise agreed.

The mechanical properties for screws as per ASME B18.2.1 are defined in accordance with the SAE J429 standard (see Table 5). Strengths are normally specified there in psi (pound-force per square inch), 1000 psi = 6,895 N/mm².

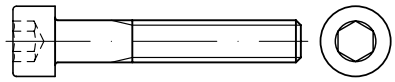
Table 6: Mechanical properties of hexagon head screws as per ASME B18.2.1/SAE J429

Property class	Grade 5 (~ 8.8)		Grade 8 (~ 10.9)
Properties	Ø > ¼ – 1	Ø > 1 – 1½	Ø > ¼ – 1
Tensile strength N/mm²	827	724	1034
psi	120.000	105.000	150.000
0.2 % yield strength N/mm²	634	558	896
psi	92.000	81.000	130.000
Elongation at fracture in %	Min. 14%		Min. 12%
Rockwell core hardness in HRC min.-max.	25 - 34	19 - 30	33 - 39
Marking of the property class			
Screws as per ASME B18.2.1 should be marked with the manufacturer's mark and the property class as per SAE J429.

Properties for fasteners made of steel with inch thread as per ASME standards

Properties of hexagon socket head cap screws as per ASME B18.3-2012 Table 1

The ASME B18.3-2012 standard regulates the properties of hexagon socket head cap screws with inch thread. The 1936 version of the standard was thoroughly revised in 1960. The head geometry had also changed. The goods supplied by REYHER comply fully with the "1960 series"; the "1936 series" can be obtained on request. The ASME B18.3 standard specifies 5 different product geometries here (including countersunk head and lower head height). The hexagon socket head cap screws (comparable to DIN 912/ISO 4762) are described in detail in the following.



The thread tolerances for inch screws are regulated in the ASME B18.1.1 standard where the following tolerances apply:

- Up to and including 1 inch: Class 3A,
- Above 1 inch: Class 2A.

The mechanical properties for screws as per ASME B18.3-2012 Table 1 are only defined in accordance with the ASTM A574 standard (see Table 6). Strengths are normally specified there in psi (pound-force per square inch), 1000 psi = 6.895 N/mm².

These screws should only be marked with the manufacturer's mark as only one property class is provided for this product. The head of the hexagon socket head cap screw can be knurled at the choice of the manufacturer. A galvanic coating should be avoided due to the high tensile strength and the associated danger of hydrogen embrittlement.

Table 7: Mechanical properties of hexagon socket head cap screws as per ASME B18.3/ASTM A574

Properties	Steel as per ASTM A574 (~ 12.9)	
	Ø ≤ ½	Ø > ½
Tensile strength N/mm² psi	1241 180.000	1172 170.000
0.2 % yield strength N/mm² psi	1054 153.000	
Elongation at fracture in %	Min. 10%	
Rockwell core hardness in HRC min.-max.	39 - 45	37 - 45

Properties of nuts as per ASME B18.2.2-2010 Table 7

The ASME B18.2.2 standard regulates the properties of nuts with inch thread. On the other hand, this standard specifies 14 different product types, thus "hex nuts" are the products that are listed as item 83934 in this catalogue.

The thread tolerances for nuts are also regulated in the ASME B18.1.1 standard; the nuts are supplied in tolerance class 2B unless agreed otherwise. These nuts can be screwed together with zinc plated and non zinc plated products.

The mechanical properties for nuts as per ASME B18.2.2 are defined in accordance with the SAE J995 standard (see Table 7). Strengths are normally specified there in psi (pound-force per square inch), 1000 psi = 6.895 N/mm².

Table 8: Mechanical properties of "hex nuts" as per ASME B18.2.2/SAE J 995

Property class Properties	Grade 5 (~ 8)		Grade 8 (~ 10)		
	Ø > ¼ – 1 UNC	Ø > 1 – 1½ UNC	Ø > ¼ – ⅝ UNC	Ø > ⅝ – 1" UNC	Ø > 1 – 1½ UNC
Tension under test force N/mm² psi	827 120.000	723 105.000	1034 150.000		
Rockwell core hardness in HRC min.-max.	≤ 32		24 - 32	26 - 34	26 - 36
Marking of the property class					

Nuts as per ASME B18.2.2 should be marked with the manufacturer's mark and the property class.

Properties of washers as per ASME B18.22.1-1965 Type A

The ASME B18.22.1 standard regulates the properties of washers for screws with inch thread. The standard essentially differentiates 2 versions: "Narrow " and "Wide". The difference between the two versions is in the larger outside diameter for the washers of the "wide" version (see table of dimension pages).

There are no requirements on mechanical properties for the "plain" version washers; they should only be produced from steel materials. An overview of washer properties is given in Table 8.

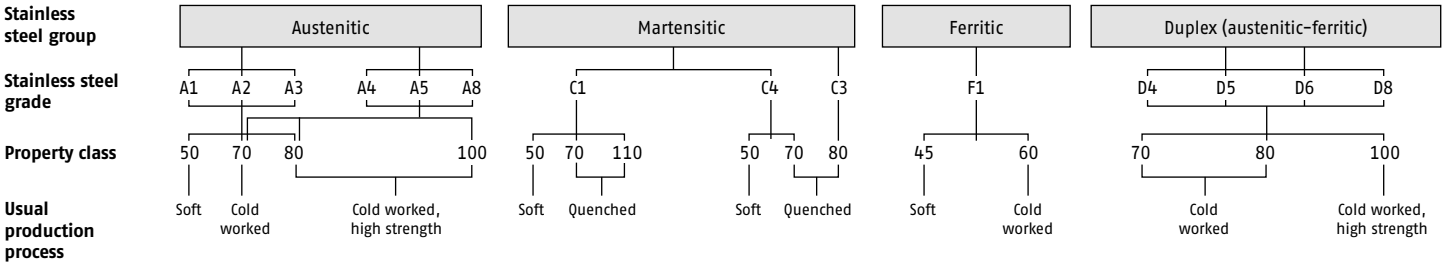
Table 9: Mechanical properties of washers as per ASME B18.22.1/ASTM F436

Properties	Plain washers	Hardened washers as per ASTM F436		
	ASME B18.22.1	Hardened, bare or ZP	Hardened, HDG	Case hardened
Rockwell core hardness in HRC min.-max.	No specification	38 - 45	26 - 45	Min. 30 HRC
Case hardness depth/case hardness HR15N - Bare/ZP - HDG				 0.015"/79 – 83 0.015"/73 - 83

Properties: Fasteners from stainless steels

The mechanical properties of fasteners from corrosion-resistant stainless steel as well as their quality inspection and marking are set in ISO 3506. Parts 1 and 2 are currently being revised, and a new part 6 (General rules for the selection of stainless steels and nickel alloys for fasteners) is under development. Extracts from these drafts and scripts are also presented here.

According to ISO 3506, stainless steels are divided into four steel groups according to their steel structure. The different steel types of stainless steels can be obtained with various materials and have different properties in terms of corrosion resistance and function.



The fasteners' surface condition (passivation ➔ ISO 16048, surface roughness etc.) may affect the corrosion resistance of the fastener. Fasteners made of stainless steels can be used in low temperature environments as follows:

- martensitic, ferritic, and Duplex steel are suitable for working environments of down to -40 °C
- austenitic steel is suitable for operating environments of down to -196 °C (screws with head down to -60 °C, headless screw down to -200 °C per DIN 267-13)

Austenitic steels (A)

Austenitic stainless steels are generally divided into austenitic chrome nickel steels (A1 to A3) and austenitic chrome nickel molybdenum steels (A4 to A8). Austenitic stainless steels cannot be hardened with heat treatment. The mechanical properties of the fasteners are normally achieved by cold working. Copper can help improve the workability of the austenitic structure.

Under the following conditions, A2 and A4 steels can be more susceptible to intercrystalline corrosion:

- the carbon content is higher than 0.030% and/or
- the steel is exposed to high temperatures (either during the manufacturing process, a welding process or in its operating environment)

In these cases, steels with a carbon content of less than 0.030% (A2L or A4L) or stabilized austenitic steels of the types A3 or A5 may be used.

A8 is a high-alloy austenitic stainless steel with significantly higher corrosion resistance compared to A4.

Austenitic steels are usually not magnetic in annealed condition, however, cold forming that occurs during the manufacturing process of fasteners, may lead to a certain degree of residual magnetism.

The steel types A1 – A3 are **not** suitable for use in oxidizing acids or in an environment with chloride (e.g. in swimming pools where chloride is used as a cleaning agent, or in marine environments).

Permeability

A 2:	μ_r P 1.8
A 4:	μ_r P 1.015
A 4L:	μ_r P 1.005

Excerpt from ISO 3506-1 Annex H

A1: Stainless steels of steel type 1 are designed particularly for mechanical processing. Due its high sulphur content this type is less corrosion resistant than the respective steels with normal sulphur content.

A2: Type A2 stainless steels are the steel types that are mostly used for compressed fasteners. They are more resistant to corrosion than A1.

A3: Type A3 stainless steels have similar properties to type A2 steels; however, their temperature resistance is increased (typically up to 350 °C) They are stabilized by adding titanium or niobium, which combine carbon and nitrogen.

A4: A4 type stainless steels are often called "acid-resistant steels", contain molybdenum as an alloy and are much more corrosion resistant. This steel type can be used in environments containing chloride, but not in swimming pool areas with chloride as a cleaning agent and not in many maritime environments.

A5: Type A5 stainless steels are stabilized steels with the same properties as A4 type steels; however they are more temperature-resistant (typically up to 350 °C). They are stabilized by adding titanium or niobium, which combine carbon and nitrogen. This steel type can be used in environments containing chloride, but not in swimming pool areas with chloride as a cleaning agent and not in many maritime environments.

A8: Type A8 steels are also known as "6% Mo" steels. They are highly resistant against all types of corrosion, including pitting corrosion, crevice corrosion and stress crack corrosion. They are suitable for use in swimming pools, where chloride is used as a cleaning agent; however, specific requirements and/or regulations for buildings and structures should be considered. They can also be applied in maritime environments.

Martensitic steels (C)

Three martensitic steel types C1,C3, and C4 are contained in the ISO 3506 standard. They can be hardened by quenching.
The mechanical properties are increased with increasing carbon content. For this reason, the chromium content is increased in order to achieve suitable corrosion resistance. The martensitic steel types are normally less corrosion resistant than austenitic steel types.
In temperatures below zero, their use shall be considered carefully, as martensitic stainless steels are less resistant to impacts and less ductile than austenitic steels. Martensitic steels are always highly magnetic.

Properties: Fasteners from stainless steels

Ferritic steels (F)
The mechanical properties of ferritic steels are achieved with cold working (cold forming), where the efficiency is however reduced in comparison to austenitic stainless steels. Ferritic steels are always magnetic. If the corrosion resistance required for a certain application can be lower than that of steel types A2 or A3, the stainless steel type F1 may be a good economic solution. Type F1 steel shall however not be used in temperatures below –20 °C, as ferritic stainless steels are less resistant to impacts and less ductile.

Duplex steels (D)
The structure of duplex steels is composed of a mixture of ferrite and austenite grains with a ferrite content of typically 40 to 60 percentage by volume. In solution heat treated condition, the strength of stainless duplex steels is considerably higher than the strength of austenitic stainless steels and can be additionally increased through cold working. However, ductility will be reduced in this process. Duplex steel types are normally described as follows:

- "Lean-Duplex" with low alloy content of particularly nickel and molybdenum (D2 and D4),
- "Standard-Duplex" (D6),
- "Super-Duplex" with high alloy content (D8).

In comparison to austenitic stainless steels A1 to A5, Duplex steels show clearly improved resistance to stress crack corrosion. Duplex steels should be applied only within a temperature range of –40 °C to +250 °C.

D2/D4: In terms of pitting corrosion and crevice corrosion, corrosion resistance of D2 is at least equivalent to that of A2, and corrosion resistance of D4 is at least equivalent to that of A4.

D6: "Standard-Duplex" contains more than 2.5% molybdenum. This helps to improve its corrosion resistance in terms of pitting corrosion and crevice corrosion in comparison to A1 to A5 and D4.

D8: The corrosion resistance of this "Super-Duplex" is comparable to that of A8.

Marking: Hexagon head, hexagon and hexalobular socket head cap screws, studs and nuts with a thread diameter of ≥ M 5 (studs ≥ M 6) are to be marked with manufacturer symbol, steel grade and property class.

Chemical resistance of stainless steel fasteners A 2 and A 4

In practice, the resistance specifications can change; the pure agents rarely have an effect, admixtures often strengthen or weaken the attack. Residue on the part can also change the conditions. The safest approach is always to check the operating conditions.

General information and tightening methods

General information

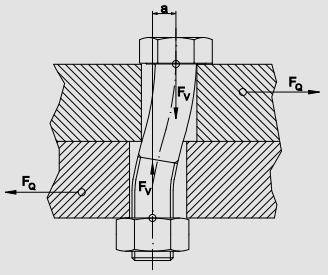
Functional quality and fatigue limit of fasteners are mainly determined with the following factors:

- Mechanical properties (tensile strength, yield strength, elongation)
- Operating conditions (static/dynamic...)
- Service conditions (temperature, corrosion)
- Dimensioning (diameter, length)
- Locking against loosening and unscrewing if necessary
- Assembly (tightening method, preload/clamp load, tightening torque...)

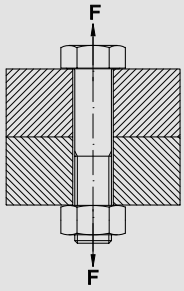
While taking into account all requirements, the task of constructive planning is to determine the suitable fasteners, to define them with the standardised descriptions and to provide the necessary assembly instructions.

The VDI guideline 2230 is available as the recognised standard reference for the "systematic evaluation of highly stressed fasteners".

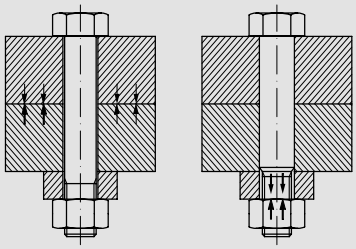
Fasteners should be evaluated and assembled in such a way that transverse loads (FQ) perpendicular to the centre of the screw do not have any effect because of the sufficiently intact clamp load under operating conditions. Here, loss of clamp load due to intrusions of parts into materials also needs to be taken into account. If the transverse loads are larger than the clamp load, this will lead to the screwed fastening loosening, and ultimately, to its failure.



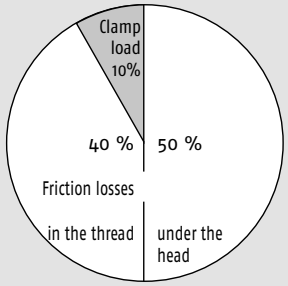
Transverse load F_Q



Preload F_V,
Clamp load F_S



Clamp load F_{KL}



Reaction ratio of tightening torque in clamp load

Tightening method

Essential for the quality and fatigue limit of a fastening is the precise setting/adherence to the assembly preload. Thus alongside the size of the screw, the property class and the friction ratios, the tightening/assembly method is of vital importance during assembly. Numerous tests and theory observations have shown that 80–90% of the tightening torque is required to overcome the friction under the head and in the thread. Only a small part is actually put into generating preload.

Differentiations are made between the following methods:

Manual tightening
In general, tightening by feel with manual tools should not be done. Even with experienced workers, the spread is very large. Empirical values show that screws/bolts up to M 12 are usually tightened beyond the yield strength, while screws over M 14 are usually not tightened enough.

Torque-controlled tightening
Tightening with a torque wrench still shows quite a large spread in the preload due to the friction coefficient differences.

Impact-controlled tightening
When assembling with impact screwdrivers, the motor power of the screwdriver in the impact mechanism is converted into tangential angular momentum. This preloaded the screw step-by-step. The advantage of using the impact screwdriver is that the worker absorbs hardly any reaction torque. The disadvantage is to be found in the numerous factors of influence on the screw preloading:

- Elasticity and friction coefficients of the screwed fastening
- Elasticity of the attached tool and the extensions
- Impact strengths and frequency duration or entire impact count

Elongation-controlled tightening
The preload can be calculated from the change in length of the screw, which, for example, can be determined using an ultrasound method during assembly. This method currently offers the highest level of accuracy. However, it is quite complex and expensive.

Angle controlled-tightening
With this method the screw is first preloaded by rotation torque then turned further by a mathematically calculated rotation angle until the ductile deformation starts. The method requires complex trials and is thus quite expensive. Furthermore, it can only be used for screwed fastenings with a long enough stretching length. The mostly ductile deformation of the screw makes it impossible to reuse.

Yield-controlled tightening
This method requires a screwing system consisting of a screwdriver, a control unit and a computer and uses the technical data for controlling, i.e. that upon reaching the yield strength of the screw, the tightening rotational torque no longer increases. The mostly ductile deformation of the screw makes it impossible to reuse.

Hydraulic tightening
Hydraulic preloading is done via the overlong end of the screw. The preloading device supports itself around the nut. The nut can be tightened in a form-fitting way or with a small amount of torque. The centre point of the hydraulic tightening is with large screws up to M 200 in system construction. For example, all screws of a flange can be tightened simultaneously which brings about a uniform distribution of load.

**Table 1: Accuracy classes of the tightening methods
Influence of the friction ratios, spread of the preloads**

Accuracy class	Spread of the preload %	Tightening factor	Influence of the friction coefficient?	Tightening method (tools)	Adjustment/Inspection method
–	± 2 to +10 ± 5 to ± 20	1.05 to 1.2 1.1 to 1.5	no	• elongation-controlled (ultrasound) • elongation measurement (mechanical)	Ultrasound sensor (PMT system) Set up and length measurement
I	± 9 to ±17	1.2 to 1.4	no	• yield-controlled • angle-controlled (power-assisted or manually)	Empirical specification of pre-tightening torque/rotation angle
II	± 9 to ± 23	1.2 – 1.6	no	• hydraulic tightening	Length/pressure measurement
III	± 17 to ± 23	1.4 – 1.6	yes	• torque-controlled (torque wrench, extension measurement, precision screwdriver)	Empirical specification of the reference tightening torque/ dynamic torque measurement
IV	± 23 to ± 33	1.6 – 2.0	yes	• torque-controlled	Reference tightening torque according to estimated friction coefficient
V	± 26 to ± 43	1.7 – 2.5	yes	• torque-controlled (screwdriver) • impulse-controlled (impact wrench)	with post-tightening torque, taken from reference tightening torque (according to estimated friction coefficient) + extra
VI	± 43 to ± 60	2.5 – 4.0	yes	• impulse-controlled (impact wrench) • manually (wrench)	without (via post-tightening torque if necessary)

**Table 2: Friction coefficients $\mu_{ges.}$
for steel screws/nuts***

Surface condition		$\mu_{ges.}$ for condition		
Male thread (screw)	Internal thread (nut/component)	non-lubricated	oiled	MoS_2-lubricated
without coating (black)	without coating	0.12 – 0.18	0.10 – 0.17	0.06 – 0.12

Preloads and tightening torque for fasteners of steel

Preloads and tightening torque for steel shank screws with full loadability with head contact area sizes like DIN 912, 931, 933, 934, ISO 4762, 4014, 4017, 4032*

The following are taken into account in table values for M_A:

a) Friction coefficient μ_{total} = 0.14*
b) Utilisation of the minimum yield strength = 90%
c) Torsion torque when tightening

(* The friction coefficient of μ_{total} = 0.14 is generally assumed for screws and nuts in standard commercial deliveries)

Additional lubrication of the thread considerably changes the friction coefficient and brings about unspecified tightening ratios! Tightening methods and tools have different spreads (→ Tab. 1/VDI 2230-1, Tab. A8).

Table 5: Typical values for shank screws/bolts with coarse thread, friction coefficient μ_{total} =0.14

Tables 5 and 6: up to M 39 extract from VDI 2230-1: 2003-02, above M 39 calculation based on VDI guideline 2230-1: 2003-02

Preloads and tightening torques for fasteners of steel

Preloads and tightening torque for steel shank screws with defined friction coefficient range* with head contact area sizes like DIN 912, 931, 933, 934, ISO 4762, 4014, 4017, 4032

*the coeficient of friction μ_{ges} is shown for the applicable fasteners on the price pages of this catalogue.

Table 7: Typical values for shank screws/bolts with coarse thread, utilisation of the minimum yield strength of 90%

Preloads and tightening torques for fasteners from steel

Preloads and tightening torques for fasteners with reduced loadability like e.g. DIN 6912, 7984, ISO 7380 -1/-2, 10642

Fasteners with reduced loadability are standardized or non-standardized fasteners with material and mechanical properties according ISO 898-1, due to its geometry, does not fulfil the test requirements for full loadability fasteners.

Fasteners with reduced loadability does not normally break in the free threaded length.

Basically, there are two geometrical reasons for reduced loadability of fasteners:

a) head design which applies to
- bolts and screws with low head with or
- without external driving feature, or
- with low round or cylindrical head with internal driving feature or
- countersunk head with internal driving feature.

b) shank design: e.g. screws with waisted shank.

The identification of screws and bolts with reduced loadability is a "0" before the property class, e.g. 08.8 or 010.9.
Fasteners according to above mentioned product standards can hold about 80% of the preloads of fasteners with full loadability.

Table 10: Typical values for fasteners according DIN 6912, 7984, ISO 7380 -1/-2, 10642, total friction coefficient μ_{ges} = 0.14

Typical values for tightening torques of screwed fastenings with SCHNORR washers
REYHER article 88120 and REYHER article 88121:
As a typical value, 10% should be added to the normal tightening torque M_A according to TI-244, Tabels 5 and 6.

Assembly of fastenings in steel constructions

Systematic preloaded connections with HV sets

The following two assembly methods for achieving the preload force are permitted in Germany for the assembly of HV sets.

Standard	Preload	Assembly method	*k* class
EN 1090-2	$F_{p,C}$ (full preload force)	Combined method	K1
DIN EN 1993-1-8 NA DAST Guideline 024	$F_{p,C}$* (modified preload force)	Modified torque method	K1

Preload forces and tightening torques for the respective methods for *k*-class K1 and property class 10.9 are listed in the following table. Refer to EN 1090-2 for the corresponding assembly steps required.

Table 18: Preloads and tightening torques for HV fastenings of property class 10.9 as per EN 14399-4 or DAST Guideline 012 with *k*-class K1

Ø	Combined tightening procedure with $F_{p,C}$				Modified method with $F_{p,C}$*

Non-preloaded structural bolting assemblies – SB sets

For the area of non-preloaded fastenings, SB sets such as e.g. ISO 4014/4017/4032/7090 but also DIN7990 and more in the future are used that, contrary to the HV system, are only hand-tightened. Screws and nuts must also be marked with "SB" for "structural bolting".

Table 22: Recommended "hand-tight" tightening torques for non-preloaded fastenings, independent of the property class of the screws according to DAST regulation 024.

Preloads and tightening torques for fasteners made of stainless steel

Preloads and tightening torques for fasteners with full loadability from stainless steel

For fasteners made of stainless steel, the friction coefficients in the thread and on the contact surfaces are much higher than with quenched and tempered steel screws. Even the spread of the friction coefficients is much higher here (up to and over 100%). To finally determine the correct torque it is recommended that testing should be carried out under operating conditions.

While it is possible to reduce friction coefficients by using lubricating agents, the very high range of variation will remain.

The table lists non-binding typical values for various friction coefficients, valid for screws and nuts according to DIN 912, 931, 933 and 934/ISO 4762, 4014, 4017, 4032 made from stainless steels A 1–A 5, in property classes –50, –70 and –80 at room temperature (approx. +20 °C) and utilisation of the minimum yield stress of $R_{p0.2}$ = 90%.

Tightening torques and preloads

for fasteners with reduced loadability from stainless steel.

Fasteners according to DIN 6912, 7984, ISO 7380-1/-2, and 10642 have a reduced loadability due to their head geometry. As a guideline for preloads and tightening torques of 80% of the values of the above table 22 can be assumed. (➔ see also TI-246)

Torque typ hexagon nuts

from stainless steels sometimes tend to jam in the locking element due to the high flank pressure when inserting the screw head. Here, treating the screw thread with an anti-friction agent usually helps.

Lubricated nuts

For optimal assembly of austenitic fasteners the use of a lubricant is recommended.

REYHER offers lubricated nuts in A2/A4 as part of our product range.

Tightening torque for fasteners made from BUMAX 88/109 brass, polyamide

Tightening torques and preloads for fasteners made from stainless steel BUMAX 88/109

Fasteners made from BUMAX 88/109 have an adjusted coefficient of friction by a specific lubrication. In contrast to this, this allows usually unlubricated fasteners made of stainless steel (A 2/A 4) are applied to targeted pre-tensioning forces.

Table 24: Typical values for fasteners made from BUMAX 88/109

Preloads and tightening torque for fasteners made from brass

For fasteners made from brass, the friction coefficients in the thread and on the contact surfaces are much higher than with quenched and tempered steel screws. In order to determine the correct torque, it is recommended that experiments should be carried out under operating conditions. It is possible to reduce friction coefficients by using lubricating agents.

Table 24 lists non-binding typical values for various friction coefficients, valid for screws and nuts according to DIN 912, 931, 933 and 934/ISO 4762, 4014, 4017, 4032 made from brass with a minimum stress at 0.2% non-proportional elongation of 250 N/mm² (e.g. MS 58 and MS 63) and utilisation of the yield stress of 90%.

The tightening torques listed in the table may **only be used as very rough and non-binding typical values.**

Tightening torques for polyamide screws and nuts

Table 19 includes non-binding typical values for appropriate tightening torques for screws and nuts made from polyamide 6.6 at 20 °C after storage in a normal climate.

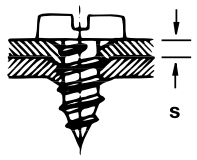
The preload can ease off somewhat as a result of relaxation processes.

Table 26

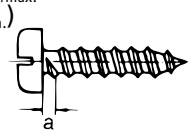
Ø	M 3	M 4	M 5	M 6	M 8	M 10	M 12	M 16
Tightening torque Nm	0.1	0.25	0.5	0.8	1.8	3.5	6.0	12

General assembly instructions

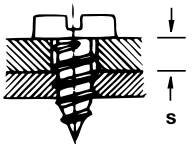
Screwing in of thinner sheet metal with continuous tapping holes or ones enlarged with a drift



Sheet metal thickness lower/upper limit* $s_{min./max.}$ ($a_{max.} = s_{min.}$)



Screwing in of thicker sheet metal with drilled or punched tapping holes



Screwable plate thickness

Ø/ST	2.2	2.9	3.5	3.9	4.2
$s_{min.} = a_{max.}$	0.8	1.1	1.3	1.3	1.4
$s_{max.}$	1.8	2.2	2.8	3	3.5

Ø/ST	4.8	5.5	6.3	8	
$s_{min.} = a_{max.}$	1.6	1.8	1.8	2.1	
$s_{max.}$	4	4.5	5	6.5	

s = sheet thickness
a = distance from head to thread

* With very thin metal sheets (< a max.) the usage of special thin tapping screws or clamping nuts (spring nuts) is recommended.

Drilling hole diameters for tapping screws

The tapping hole diameters in the following tables are non-binding approximate values for round holes.

The values may differ depending on the material or assembly conditions – this applies in particular to screws made from non-hardenable, stainless steels of the austenitic material groups A 2/A 4 (→ ISO 3506-4).

When using synthetic-based screws, the following conditions apply.

Table 27: Drilling hole für tapping screws

Nominal thread diameter d_1	Drilling hole-Ø (Tol. H 12) for tapping screws from material							
	for sheet thickness s		Hardened steel (min. 450 HV)				Stainless steels A 2/A 4 (ca. 250 HV)**	
			Drift-enlarged/Continuous hole Sheet from material		Drilled/Punched hole Sheet from material		Sheet from material

For "Mechanical fasteners" (screws, nuts and accessory parts), all function-relevant external and internal characteristics are regulated in detail in DIN, ISO or EN standards, this includes:

- **Product standards** (e.g. DIN 931/ISO 4014)
  Specifications on the figure of the product, assigned version and product class (tolerance group), usual strength classes and/or materials and nominal sizes. Furthermore, each product standard contains "normative references" to relevantly applicable basic function standards.

Basic/Function standards (e.g. DIN 13, 267/ISO 898, 4759, 3269...)
Regulations for joint characteristics of the various products such as e.g. thread, tolerances, surface versions, corrosion protection, mechanical properties and corresponding factory test programme as well as acceptance testing conditions.

By naming an article with a product standard number, all referred basic standards are automatically included and applicable as "Technical Delivery Conditions". This also applies for non-standardised thread and form parts when no particular arrangements have been made between the orderer and the supplier.

Standards always can only regulate just one general standard for products "for general use", this also applies for "Mechanical fasteners" (➔ ISO 3269/8992). For higher requirements for specific cases exceeding these normative regulations, it is the job of the user to define these requirements and specify necessary additional inspection requirements.

1. Quality checks during manufacture:
For basic/functional standards, testing programmes and procedures are given within which the manufacturer has to ensure the compliance with the proper standards quality of its products by carrying out constant sample checks. Alongside the obligatory checks for dimensional accuracy and surface condition, the following checks are also listed, among others:

- for screws and similar thread parts (➔ e.g. ISO 898-1)
  - hardness testing, proof load testing
  - bolt head impact/diagonal pull testing
  - surface decarburisation testing
- for nuts (➔ e.g. ISO 898-2)
  - hardness test, proof load test
  - expansion test

The procedure to be used in arbitration is specified in the standards. All standardised mechanical properties are generally valid at room temperature (approx. +20 °C).

2. Additional tests – Certificates

For particular requirements and/or safety-related use cases, additional articles or use-specific tests can be carried out either in the factory or by a commissioned factory independent technical expert or testing institute. The results of these extra tests shall be documented in a test certificate.

The type and scope of these additional tests and who is to carry out and document them is to be determined by the user due to his knowledge on the use and particular requirements, and specified accordingly upon ordering. The costs for additional tests are usually not part of the product price.

2.1. Inspection documents according to ISO 16228

For fasteners, ISO 16228 was released in May 2018 and replaces DIN 11204. This standard regulates the various types of inspection documents for fasteners, and it also contains 4 document types according to ISO 10204, starting with F (for fasteners), i. e. F2.1, F2.2, F3.1, F3.2. Furthermore, the scope of content of inspection documents for fasteners is specified and can be applied to finished fasteners such as bolts, screws, threaded bolts, nuts, washers, pins, rivets, and so forth, made of steel, stainless steel, non-ferrous metals or non-metallic material. In the inspection documents (F2.2, F3.1, F3.2) all inspection results are taken over from the certificates of the material suppliers and/or the reference inspections on the finished fasteners. In case of F3.1 this can be made by the actual manufacturer or the distributor. ISO 16228 is thus a useful summary of EN 10204 and DIN 11204 and facilitates the handling of inspection documents for fasteners.

2.2. Inspection contents according to ISO 16228 (former DIN 11204)

If there are no specifications on the scope of the test contents agreed in the order, ISO 16228 shall apply.

Table 1 – Test contents for fasteners (excerpt from ISO 16228)

Screws	Type of test	
	Material properties/ mechanical and physical properties	functional properties
Screws ISO 898-1	Chemical composition except for F2.2 (M) tensile strength a) (M) hardness for quenched property class (M)	Thread reduction (A)
Screws ISO 3506-1	Chemical composition except for F2.2 (M) tensile strength and elongation after fracture (M) hardness for fasteners made of martensitic and ferritic stainless steel (M)	Thread reduction (A)

Nuts	Type of test	
	Material properties/ mechanical and physical properties	functional properties
Nuts ISO 898-2	Chemical composition except for F2.2 (M) test load a) (M) hardness for quenched property class (M)	Thread reduction (A)
Nuts ISO 3506-2	Chemical composition except for F2.2 (M) test load a) (M) hardness for fasteners made of martensitic and ferritic stainless steel (M)	Thread reduction (A)

(M) = Measurement, (A) with attribute test

a) If possible, the tensile strength of mechanical fasteners shall be tested on whole screws according to the FF test programme as per ISO 898-1. If none of the tensile inspections specified in ISO 898-1, the substitute inspection that has to be performed, shall be agreed at the time of order placement.

General information:

- The values determined by additional testing and documented in certificates are not "committed properties" or "guarantees of quality" according to Section 267 of the German Civil Code (BGB) and do not mean that the user does not have to perform the proper inspection of incoming goods (Section 377 of the German Commercial Code (HGB)).
- All tests named in 1 and 2 are carried out in general on samples. While their results are representative for the most part of the delivery batch of a load, a 100% guarantee for each part of the batch can be derived from this just as little as its suitability for a specific purpose can be.

Table 2: Overview of the usual inspection documents for screws, nuts and accessory parts according to ISO 16228
Excerpt from ISO 16228 – 05.2018

Type and name of test certificate for mechanical fasteners		When	Content	Confirmed by
F2.1	Declaration of Conformity for fasteners	requested on ordering	Declaration of Conformity for delivered fasteners, no results	Authorized representative of manufacturer or distributor
F2.2	Inspection certificate for fasteners	requested on ordering	Declaration of Conformity for delivered fasteners, with results on the basis of non-specific tests	Authorized representative of manufacturer
F3.1	Inspection certificate for fasteners	requested on ordering	Declaration of Conformity for delivered fasteners, with results of specific tests	Authorized representative of manufacturer or distributor
F3.2	Inspection certificate for fasteners	requested on ordering	Declaration of Conformity for delivered fasteners, with results of specific tests	Authorized representative of manufacturer or distributor and either an authorized representative of the buyer or an external authorized representative

not recommended since there is no specific statement on the delivered product.
the sample quantities for destructive inspections are to be taken into account when deciding the order quantity
e.g. TÜV, GL, DB ...

3. Acceptance testing for "Mechanical fasteners" according to ISO 3269

This standard is always included as applicable when "Mechanical fasteners" are ordered according to standard or similar form parts, if not expressly agreed otherwise beforehand.

It does not apply to fasteners which

- are intended for automatic screw-in,
- are supposed to fulfil particularly high requirements,
- require particular processing procedures/testing measures,
- require specific traceability.

Here, special corresponding arrangements always need to be made on request, on ordering at the latest (e.g. according to ISO 16426). In general, standard commercial stock is not suitable for these specific requirements.

The final draft ISO 3269 – FprISO 3269:2019 now defines scopes of random samples, acceptance numbers and rejection numbers for certain test categories. The test categories are allocated to certain characteristics. Tables 3 and 4 show an extract from this draft with the most important details.

Table 3: Sample test scope, acceptance number N_A and number of rejections N_R
per FprISO 3269:2019

Batch size	Category 1	Category 2		Category 3
		Initial sample test	Additional sample test	
	N_A=0 N_R=1	N_A=0 N_R=2	N_A=0 N_R=1	
2 to 50	1	4	4	not applicable
51 to 90	1	5	5	5 N_A=1 N_R=2
91 to 150	1	6	6	6 N_A=1 N_R=2
151 to 280	1	7	7	7 N_A=1 N_R=2
281 to 500	2	9	9	9 N_A=1 N_R=2
501 to 1200	2	11	11	11 N_A=1 N_R=2
1201 to 3200	2	13	13	13 N_A=1 N_R=2
3201 to 35000	3	15	15	15 N_A=2 N_R=3
35001 to 500000	5	20	20	20 N_A=2 N_R=3
more than 500 000	8	20	20	20 N_A=2 N_R=3

Table 4: Test categories according to FprISO 3269:2019

Test category	Description
Category 1	Characteristics, for which the acceptance number N_A is zero. Category 1 characteristics comprise all mechanical and functional properties that are usually tested with destructive testing. In case deviations are detected during random sampling, the batch or delivery will be rejected.
Category 2	Characteristics, for which the acceptance number N_A is zero; however, in case of deviation, a second sample may be taken. Category 2 characteristics are important dimensional characteristics, which may have negative effects on fit or function of the fastener. If, however, a single deviation is detected in the first sample, another sample with regard to this respective characteristic shall be tested, the scope of which shall correspond to the first sample. If no deviation is detected in this additional sample with regard to the respective characteristic, the batch will be accepted.
Category 3	Characteristics, for which the acceptance number N_A matches one or more deviations, as indicated respectively. Category 3 characteristics are minor dimensional characteristics and certain functional properties, for which deviations are tolerated to a certain extent. In case more deviations are detected during random sampling than those stated as acceptable, the batch or delivery will be rejected.

Test method: Hardness measurement and notch impact test

The hardness measurement serves to determine the resistance of a material against the penetration of a test specimen which acts upon it with a specific type, force and time. Depending on the applied procedure, the hardness value is determined from the measured depth or size of the impression the test specimen makes on the workpiece.

The most common standardised methods are shown in Table 1. If in doubt, the Vickers Hardness test shall be applied for the mechanical fasteners. The measurements are taken on prepared samples. Here it needs to be differentiated between:

- **"Routine testing"**
  The measurement is taken on an even cut on the surface of the sample. Common hardness test procedures are Rockwell (HRC) and Vickers (HV 10 – HV 30).
- **"Arbitration testing"**
  The measurement is taken on a lengthwise or diagonal polished section of the cut-up specimen. The testing procedure according to ISO 898 is Vickers (HV).

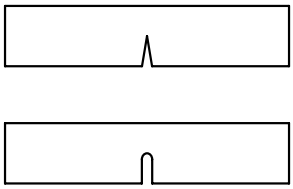
With the acceptance test of "Mechanical fasteners" hardness measurements are only part of routine and comparative checks. They are not themselves decisive for determining mechanical characteristics.

For screws, the tensile test determines the tensile strength, yield strength limit and elongation. For nuts, proof load tests and expansion tests are applicable. (ISO 898-1, DIN 267-21, ISO 898-2).

Table 2 shows a conversion of the hardnesses according to Vickers, Rockwell and Brinell into each other and for the tensile strength of non-alloy to low-alloy steels in hot-formed or heat-treated conditions. Beside these, the hardness ranges of screws, nuts and washers of the various strength classes are specified according to the standard.

Low load-hardness testing
The low load-hardness test with test loads between 2 and 30 N (HV 0.2 to HV 3) is the link between the conventional hardness testing (HV 5 to HV 100) and micro-hardness testing. It is suitable for determining the hardness in surface layers and for absorbing hardness gradient curves. For fasteners, especially quenched and tempered screws from property class 8.8 or higher, the low load-hardness testing according to ISO 898-1 is used to determine the carburisation state in the thread range.

Impact testing
Impact testing is used to measure the toughness. This shows the extent of the damage which needs to be done in order to shatter a sample. Tough steels can absorb a lot. Brittle steels require less effort. The result of impact testing is used in particular to estimate the usability of steel at low temperatures.
For testing, quadratic test specimens with a defined chamfer are made out of the screws. ISO-V and ISO-U samples are distinguished from each other. In practice, using the ISO-V sample was approved as this reacts more sensitively to the embrittlement of the screw due to the stronger notch effect compared to the ISO-U sample.



ISO-V- and ISO-U-sample

Table 1: Comparison of hardness measuring procedures

Procedure, Marking	Vickers HV	Brinell HB	Rockwell HRC	Rockwell HRB
Norm, Standard	ISO 6507-1.2 (DIN 50133)	ISO 6506 (DIN 50351)	ISO 6508/EN 10004 (DIN 50103-1)	
Suitable for materials	Metallic materials with very low to very high hardness level (specification of medium hardness)	Metallic materials with very low to high hardness level (specification of partial hardness)	Hardened steels, hardened and tempered alloys	Materials of medium hardness, steels with low to medium C-content of brass, bronze ...

* Limitations according to ISO 18265 need to be taken into consideration.
** Hardness ranges differ according to the dimension ranges in min./max. values

Screwed fastenings should be designed in such a way that the preload applied under working stress remains as intact as possible.
While in some cases a clear drop in preload can indeed be tolerated, the screwed fastenings coming undone completely must be prevented.

Mechanism of independent loosening

Creep
Time-dependent exceeding of material yield strength

Settling
Balancing of intrusions in the surface

Relative movement
between the contact surfaces

until final balance:
inner loosening torque ≤ self-retention torque

until connection comes undone completely due to the self-retention torque compensation

Loosening

Independent unscrewing

Loss of preload

Measures

Maintain frictional contact (preload)

Avoid unscrewing

Avoid connection from coming undone

Reduce bearing stress

Balance intrusions

Create material bond

Create form fitting

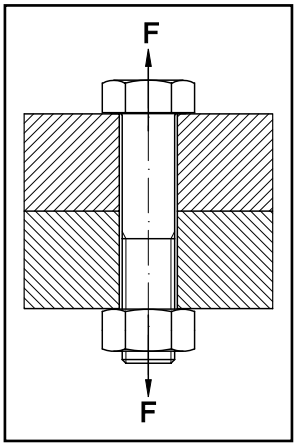
Increase self-retention

Provide locking device against loosening

Provide locking device against unscrewing

Provide locking device against losing

Source: DIN 25201-4



Loosening

Risk
Static loads in axial direction due to assembly forces and/or first operating loads may lead to settling losses. This may lead to a complete loss of preload in the screwed connection.

Settling is not only dependent on forces applied, but also on the number and shape of the separation joints between the tensile building components and the surface condition of the component, such as roughness or coating layers. Low strength of the component may also cause settling, which is caused by yield/creep of the soft material.

Measures
Loss of preload may be counteracted with certain constructive measures or by using screw-settling locks.
To keep settling losses in a screwed connection as low as possible, the number of separation joints between the building components are to be kept to a minimum. Every unnecessary washer is an additional separation joint. The insertion of "soft" washers according to DIN 125 with a hardness of 140 HV in a high-strength screwed fastening with screws of a property class of ≥ 8.8 is to be avoided.

By selecting a longer screw grip length, e.g. by using extension sleeves, preload losses can be absorbed by greater elastic elongation. The same effects are achieved by using shank expansion screws or screws with full thread or by using higher preloads from higher-strength materials.

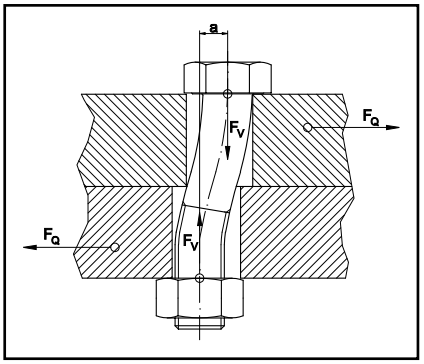
If these measures cannot be used, a curved washer can be used in accordance with DIN 6796 to partially balance out intrusions of parts into materials. Here, it should be made sure that the building component onto which the curved washer is placed is strong enough to not move under the strain and that the curved washer does not dig into the building component.

Independent unscrewing

Risk
If dynamic loads in lateral direction are large enough to shift the fastened component to each other, a loosening torque is generated which can overcome the self-retention in the threaded joint and in the bearing areas. Depending on the frequency in change of load direction, the joints will systematically loosen until they come apart.

Measures
Depending on the structural conditions, either constructive measures or locking devices are applied. The following measures may be applied (see also DIN 252014).

- Increase in initial load (preload)
- Increase in elasticity of the screw
- Increase in friction at the bearing areas of screw and nut and/or in the threaded joint
- Limitation of lateral slipping (use of fit bolts or pins)
- Use of locking fasteners in order to avoid relative movement of screw or nut
- Bonding (liquid adhesive or encapsulated adhesive)



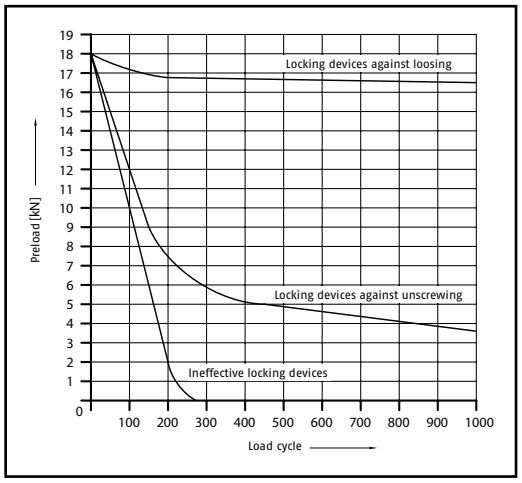
Locking of screwed fastenings

Locking devices against losing

While locking devices against losing do not prevent significant loss of preload, they do prevent the joint from coming apart completely. Usually, around 20% of the preload remains. The working principle is based on the gripping action in the thread. Nuts and screws with locking element or coating, thread rolling screws, all-over coating, strip coating or spot coating are used as locking devices against losing in practice.

The requirements for locking coatings on screws are specified in DIN 26728.
The functional properties of nuts with locking elements (prevailing torque nuts) are defined in ISO 2320.

Locking devices against losing are nuts and screws with locking element or as well as thread rolling screws.



Locking device against unscrewing

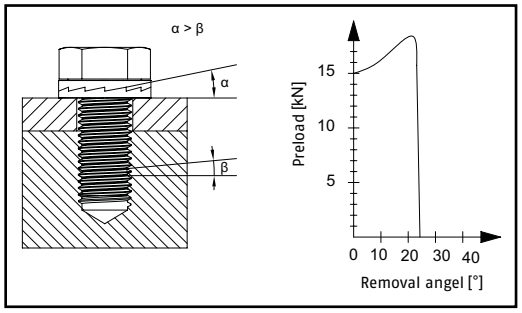
Unscrew locking devices describe elements and methods which are made fundamentally for maintaining the preload in the screwed fastening despite strong dynamic loads to avoid the screwed connections from coming apart. Normally, this prevents the preload from dropping below 80% of the assembly preload. The following basic locking methods are possible:

- Formfitting locking devices against unscrewing
- Locking through increase in preload
- Adhesive locking devices against unscrewing

Formfitting locking devices against unscrewing

Form fitting is achieved by using locking serrations or ribs on the supporting surfaces of the screw head or nut. The use of washers with locking serrations or ribs is also possible. Of particular importance here is that the surface hardness of the locking serrations/ribs be considerably stronger than the building components to be connected so that they can dig themselves into the surface. It should be noted that the serrations and ribs strongly affect the friction coefficients.

As such, much higher friction coefficients (μ_{total} = 0.2–0.3) need to be considered when dealing with soft contact materials such as aluminium alloys and construction steels, into which the serrations dig. The tightening torques need to be determined accordingly in order to achieve the desired preloads. Ultimately, the optimum tightening torques are to be determined by testing in environments which reflect the actual conditions. Typical values for tightening torques can be found on the TI pages TI-247.

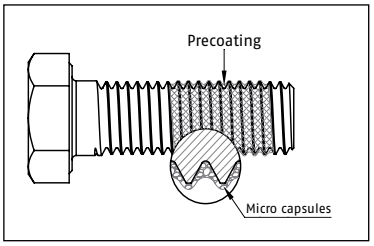


Locking through increase in preload

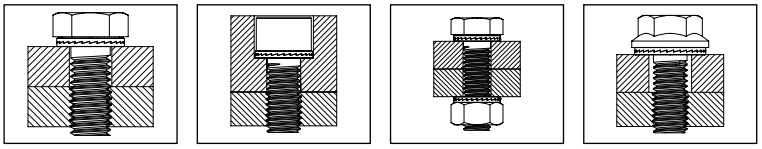
With this locking method, the exterior radial ribs of the self-locking washers are embossed into the respective component surface. In case of dynamic load and the related unscrewing attempt of the screwed connection, only a movement between the inner wedge surfaces is possible.

Due to the washers' increased wedge angle compared to the screw thread pitch angle the preload in the connection is increased, which is shown clearly in the following two figures.

Adhesive locking devices against unscrewing



In an adhesive locking device against unscrewing, micro-capsules are applied on the thread with a carrier material. These contain the adhesive and a hardening agent. The capsules break open during screwing and the adhesive begins to harden. The hardening process usually takes 24 hours to complete. A screwed fastening results which is locked against vibrations and loss of preload and which simultaneously acts as a sealant. The adhesive creates a bonded connection, which prevents unscrewing as well as locking by form fitting. DIN 267-27 describes the adhesive coating with encapsulated adhesive. Since the micro-capsules are applied to the thread in a special coating process, it is recommended that this be used especially with bulk amounts. When applying micro-capsule adhesives to zinc flake coatings, seals and/or coatings with lubricant additives, a reduction in the breakaway torques vis-à-vis DIN 267-27 may come about. In this case, the application should be safeguarded by testing in application conditions before using in bulk. The shelf life of micro-encapsulated coatings according to DIN 267-27 is determined to be at least 4 years from date of manufacturing. For smaller batches and universal use, anaerobic hardening liquid adhesives are suitable. They are applied to the thread when assembling the screwed fastening and harden when atmospheric oxygen and metal (iron and copper ions) come into contact with each other. The temperature resistance of adhesive coatings is limited. For more information please refer to TI-258.



Installation examples

Assembly instructions for form-fitting and preload-increasing locking device against unscrewing

The connection must be locked under the screw head and under the nut in order to prevent unscrewing. The figures show which versions are possible.

Information on the use of austenitic and stainless steels

Austenitic steels of the steel groups A1 to A5 do not have any spring-hard properties. Therefore, the locking elements made of these steels cannot balance any intrusions with a spring effect. Steels 1.4310 and 1.4568 represent an alternative.

Other than the steels A 1 to A 5 have partial spring-hard properties, which, however, do not fulfil the requirements for spring steel in full. For this reason, locking elements made of these two steels can obtain the spring properties of steel products only to a limited extent.

Comparison of locking and adhesive coatings

Adhesive bonding

Product/Description	Colour	Temperature resistance, locked [°C]	Thread friction coefficient µ	Curing time [h]	Property
Precote 30	yellow	-60 to +150	0.10 - 0.15	6	medium strength, sealing
Precote 80	red/green	-60 to +170	> 0.25	6	high strength, sealing

Help for selecting the correct locking device

Design objectives	Locking elements
Reusability	Form-fitting locking elements
Defined/constant friction coefficients	Nord-lock washers, adhesive locking devices
Low assembly costs	Flange screws and nuts with locking serrations/ribs, adhesive locking device
Readjustability of the fastenings	Form-fitting locking elements
Assembly conditions	If it cannot be avoided that the threads to be coupled are free from oil and grease, form fitting locking devices shall be preferred.
Temperature	Depending on the product, adhesive locking devices can bear temperatures between 110 and 200 °C maximum – see overview on page 13. Otherwise metal locking devices are recommended, which lock by form or friction.

Table 3: Overview of locking devices against unscrewing in the REYHER product range

REYHER article			Special properties
88130 – 88131	Lock rings		Duplex structured surface and bulging ➔ this also balances out small intrusions of parts into materials
88123 – 88126	Lock washers		To a certain extent, bulging also balances out intrusions of parts into materials, similar to conical spring washers.
88120 – 88121	SCHNORR safety washers		Duplex serrated surface and bulging ➔ this also balances out small intrusions of parts into materials
88132 88032 88033	Nord-Lock washers – Standard – SP (enlarged outer Ø) – SC for HV connections – Nord-Lock X-series		Each consisting of one washer pair, stuck as a pair for easy assembly. The external surfaces have ridges which are embossed into the surface of the components. The interior surfaces are wedge-shaped. During assembly, the interior surfaces only slide on top of each other ➔ this means that the friction coefficient remains constant, which makes it possible to determine a precise specification for the tightening torque. The Nord-Lock X-series washers are additionally convex. This also balances out small intrusions of parts into materials.
88034	Wedge lock nuts		With captive wedge lock washer fixed to a flange nut with a plastic ring. ➔ for easier assembly
88119	LOCKTIX washers		Duplex structured surface and large bearing area.
88912 88913 88914	Flange screws Flange nuts		The assembly process is made easier thanks to the pressed flange with ribs as individual washers do not need to be used.
88933 88934	Locking screws Locking nuts		The assembly process is made easier thanks to the pressed flange with serrations as individual washers do not need to be used. The special design of the flange balances out intrusions of parts into materials to a limited degree.

EC Directive 2000/53/EC on end-of-life vehicles (ELV Directive)
(End-of-Live-Vehicles)

The aim of this European directive is to avoid having materials which are dangerous to health in vehicles or to prevent this from happening as much as possible.
All cars and utility vehicles up to 3.5 t, which were put into operation from 1st July 2007 onwards are affected by this.

The following are banned from this date

1. Lead
2. Cadmium
3. Chromium (VI)
4. Mercury

Exceptional approval was granted until 1st July 2008 for hexavalent chromium in corrosion protection layers for screws and nuts to fasten parts of chassis frames.

This EC directive was adopted into German law through the end-to-life vehicles directive.

The automotive industry implemented the requirements of the EC directive in the form of

1. VDA data sheet 232-101 (list of materials which must be declared)
2. International material data system (IMDS)

The IDMS is a portal on which all environmentally relevant information in the supply chain are summarized and reported to the vehicle manufacturer.

➔ **These products from the REYHER catalogue comply with this directive**
All products made of steel, stainless steel and non-ferrous metals uncoated or zinc-plated with blue/transparent thick layer passivation, with zinc flake coatings without hexavalent chromates (flZnnc) and hot dip galvanization

EC Directive 2011/65/EU on electrical and electronic equipment (ROHS directive)
(Restriction of Hazardous Substances)

The Directive 2011/65/EU on the restriction of the use of certain hazardous substances in electrical and electronic equipment has been updated with the Directive 2015/863/EU (RoHS III).

It is implemented by the Electrical and Electronic Equipment Ordinance (ElektroStoffV) in Germany. According to this ordinance, waste electrical and electronic equipment, including cables and spare parts that contain more than 0.1 percent by weight of lead, mercury, hexavalent chromium, polybrominated biphenyls or polybrominated diphenyl ethers or more than 0.01 percent by weight of cadmium per homogeneous material may not be placed on the market. For certain substances and applications there are exceptions.

For lead as an alloying element there are exemptions applicable according to Annex III:

- 6(a) -I (steel up to 0.35%, galvanised steel containing up to 0.2% by weight)
- 6(b) -I (as an alloying element in aluminium containing up to 0.4% lead by weight)
- 6(c) -I (copper alloy containing up to 4% by weight)

➔ **These products from the REYHER catalogue comply with this directive**
To this current date, products that are marked with the RoHS symbol on the price pages do not contain amounts of any hazardous substances exceeding the above-mentioned limit values or are exemptions according to Annex III. If there are products that are not marked with this symbols, these might contain amounts of the mentioned substances exceeding the limit value. More detailed information is available on request.

ZEK 01.2-08 PAK
(Polycyclic aromatic hydrocarbons)

This directive replaces directive ZEK 01-08. Products (technical work equipment and consumer products) must comply with legal requirements to avoid any risk to health, such as § 30, 31 LFGB, the Chemicals Prohibition Ordinance and

§ 4 the Equipment and Product Safety Act (GPSG), which is why the revised PAH test specifications as well as the new PAH maximum values were specified in this document. Materials that may contain PAHs are, for example, elastomers (plastics and rubber materials), black or dark-coloured polymers, coatings and lacquers as well as materials treated with preservatives (naphtalene) such as natural bristles, leather products, bast and wood.

The main causes of PAH contamination in materials are the use of:

- PAH-contaminated softening oils in rubber and flexible plastics (soft plastics)
- PAH-contaminated soot as a black pigment used in rubber, plastics and varnish

This shows that products we delivered which were made of steel, stainless steel and non-ferrous metals including all coatings are not affected by this regulation.

➔ **All products from the REYHER catalogue comply with this directive**

California Proposition 65
(The Safe Drinking Water and Toxic Enforcement Act of 1986)

California Proposition 65 is a Californian law to protect drinking water sources from contamination with chemicals known to cause cancer and/or birth defects or other reproductive harm. This law does not prohibit any substances, but sets limit values for exposure to certain substances. It requires businesses to provide "clear and adequate" warnings to individuals prior to exposure to listed chemicals. These chemicals can be in the products that people purchase, in their homes or workplaces, or that are released into the environment.

The list of chemicals causing cancer and/or birth defects or other reproductive harm is maintained by the Office of Environmental Health Hazard Assessment (OEHHA),and updated every year. Currently, it contains more than 900 chemicals.

SJ/T 11364-2014 (China RoHS 2)
(Administrative Measures for the Restriction of the Use of Hazardous Substances in Electrical and Electronic Products)

The China RoHS 2 is very close to the EU RoHS and can be compared to the EC Directive 2011/65/EU (RoHS 2). According to the China RoHS 2, waste electrical and electronic equipment that contains more than 0.1 percent by weight of lead, mercury, hexavalent chromium, polybrominated biphenyls or polybrominated diphenyl ethers or more than 0.01 percent by weight of cadmium per homogeneous material. Other than the EU RoHS, the China RoHS 2 does not state exemptions. That is why products, that are in compliance with the EU RoHS, do not automatically fulfil the China RoHS conditions. China RoHS 2 requires that all electronic and electrical products that are sold in the People's Republic of China be marked with a label. The "e" label is applied to products that do not contain any hazardous substances exceeding concentration limits. Products that contain certain hazardous substances are marked with an orange label and can be used safely during its environmental protection use period (as indicated by the number in the center) which should enter into the recycling system after its environmental protection use period. In the case of the orange label, the amount of substances to be declared shall also be stated on the component or, in case of limited space, in the user manual. This indication must be made in Mandarin.

Conflict minerals
(Dodd Frank Act)

With the 15th title of the Dodd Frank Act the use of "conflict minerals" shall be avoided that are originating in or near the Democratic Republic of the Congo and are benefiting armed groups in the area. The relevant raw materials comprise tin, tantalum, tungsten, and gold from the African Great Lakes region including the Democratic Republic of the Congo, Angola, Burundi, Rwanda, Tanzania, Uganda and the Central African Republic of Zambia. According to section 1502 Dodd-Frank Act, companies that, according to US legislation, are required to issue annual reports on their stock trade to disclose whether so-called "conflict minerals" required for manufacturing products are originating in or near the Democratic Republic of the Congo. This way, all companies are affected that are allocated allong the supply chain of companies listed on US stock exchanges,
be it as a direct supplier or intermediate supplier. The material data communication in the supply chain is made via a CMRT template, that we will gladly send to you upon request.

EC Regulation EC 2006/122 (PFOS)
(Perfluoroctansulfonate)

The EU directive 2006/122/EC relates to the use of perflouroctane sulfonates (PFOS). PFOS are mainly used in the aerospace, semiconductor, and electronics industries, as well as in the photographic trade. If emissions into the environment and exposure in the workplace can be reduced to a minimum, there is no serious threat to the environment or to human health. According to the directive, special attention needs to be given to galvanic processes and surface treatment of metals and plastics. There are indications and experience shows that legislative measures are to be expected in this regard. By using the best technology available, it is expected that emissions shall be reduced accordingly. Another proposal is for restricting semi-finished products and products containing PFOS to which PFOS were intentionally added. The directive would apply only to new products and not to products that are already on the market. Since perfluoro-octanoic acid (PFOA) and its salts pose a similar risk, possible additions to this directive with regard to this group are to be expected. A fully galvanized product does not contain any measureable quantities of PFOS.

➜ All products from the REYHER catalogue comply with this directive

EC Regulations 1907/2006 – Chemicals regulation (REACh)
(Registration, Evaluation, Authorisation of Chemicals)

This EC regulation centralises and simplifies Europe-wide chemical laws through registration, evaluation and authorisation and came into effect on 1st June 2007. It is the dedicated objective to increase the level of knowledge of the dangers and risks which arise from chemicals. Here, companies are given more responsibility for the safe handling of their products. Although fasteners are in principle included as articles by the REACh regulation, most fall under exemptions and are thus exempt from the registration requirement.

According to Article 3 of REACh regulation fasteners are articles. Articles are objects, whose function is defined not by its chemical composition (e.g.by the metal components in the alloy), but by their external shape.

However, according to Article 7, Section 1 REACh regulation articles are only subject to registration if they also contain substances that are intended to be released. This is however not the case for fasteners.

Even fasteners with corrosion protection coatings, which thus have a sacrificial coating, i.e. a coating which is sacrificed to protect the component part, is not subject to having to be registered. This is because the protective layer is not released as such, but only certain reaction products. What is relevant is the exemption under Article 2 section 7 (b) REACh regulation in conjunction with Annex V section 3 of the REACh regulation. According to this, the substances which result from a chemical reaction occurring upon end use of other substances, mixtures or articles and which are not themselves manufactured, imported or placed on the market, are exempted from the obligation to register.

However, this does not affect provisions regarding substances of very high concern (SVHC) (Articles 57, 59, Annex 14 REACh regulation) in articles under Article 7 section 2 REACh regulation. These substances are not subject to registration, but must be reported, provided

a) the substance is present in those articles in quantities totalling over one tonne per year per producer or importer
b) the substance in these articles contain a concentration of more than 0.1% (by mass).

The statements above do not apply to chemical/technical products (e. g. aerosols, adhesives and sealants). These are preparations, not articles. For preparations it is not the preparations themselves, but the ingredients that are subject to registration. For products manufactured in the EU this obligation to register affects the manufacturer and the importer for imports from non-EU countries.

Next to the obligation to register and report, the REACh regulation also describes an obligation to inform according to article 33. Every supplier of every product, which contains at least one substance listed according to Article 59 (SVHC) in a concentration of more than 0.1% (by mass), must inform all participants within the supply chain. In doing so at least the name of the substance must be given. The list of substances according to Article 59 is revised and extended every half year. The Court of Justice of the European Union decided on the concept of articles, 10th September 2015 "Once and article – always an article". This means that each individual article and not the number of articles a product is composed of, serves as a reference for determining the obligation to inform. If a product contains more than 0.1% (by mass) of an SVHC candidate and thus be subject to information obligation this does not affect the production, distribution or processing of the product.

On 27th June 2018 lead (CAS-No. 7439-92-1, EG-No. 231-100-4) was added to the list of SVHC candidates, and some of our products are affected. Lead may be contained as an alloy in machine elements > 0.1 percent per pass in the following property classes/materials:

-Property classes: 4.6, 4.8, 5.8, 6.8, 04, 4, 5, 6, 11H, 14H, 17H, 22H, 33H, 45H
-free cutting steel
-copper alloys (e.g. brass, bronze)
-Aluminium alloys

Although lead has been classified as a substance causing reproductive harm, this does not mean that materials containing lead represent imminent danger. Apart from that, the potentially toxic properties of lead have been known for years and must be considered depending on the use.

➜ **The following products from the REYHER catalogue do not contain any SVHC**
All products marked with a "REACh SVHC free" symbol in the price pages do currently not contain any SVHC candidate in a concentration of more than 0.1% (by mass). If there are products that are not marked with this symbol, these might contain SVHC candidates in concentrations of more than 0.1% (by mass).

EC Construction Products Regulation 305/2011/EU
(Construction products directive)

On 1st July 2013 this regulation repealed Construction Products Directive 89/106/EEG.

This regulation defines the conditions for the marketing and provision of construction as well as their CE marking.

For more detailed information, please refer to the REYHER special publication "Fasteners Metal and Steel Construction"

➜ **These products from the REYHER catalogue comply with this directive***
- Fasteners for steel construction: EN 14399-4, EN 14399-6, EN 14399-8, DIN 7968, DIN 7969, DIN 7989, DIN 7990, Sets from ISO 4014/4017 according to EN 15048.
- Fasteners for steel construction:
  - o Chipboard screws: REYHER Article numbers 89096 – 89098, SPAX articles
  - o Wood building screws: REYHER Article numbers 89091, 89092
  - o Hexagon wood building screws: REYHER Article numbers 89571, 89092
  - o Bolts with hexagon nuts: REYHER Article number 89601

EC Directive 2006/42/EC
(Machinery Directive)

The **Directive** regulates a unified protection level for accident prevention when bringing machinery into circulation inside the European Economic Area (EEA).

This Machinery Directive is supposed to reduce non-tariff barriers in the Union. Like all directives decreed on the basis of the EC Treaty, the Machinery Directive does not have any direct effect. It needs to be adopted into national law. In Germany, this has been done by the Equipment and Product Safety Act (Geräte- und Produktsicherheitsgesetz (GPSG)) and the Machinery Directive based thereon (9th GPSGV).

From **29th December 2009** the new Machinery Directive is to be applied in a binding fashion.

Essentially, the following change were made:

- Clearer restriction of the scope of application for the low-voltage directive and for the lift directive
- Incomplete machinery are included in the scope of application. Which directive requirements were satisfied can be found in the related documents. Included in the scope of delivery are a declaration of installation and assembly instructions written in the language of the country.
- The basic health and safety requirements were modified to meet technical advances made
- Selection options for conformity assessment procedures for machinery with inherently dangerous machines (see Annex 4 of the directive)
- Safety components receive the CE marking
- Inclusion of household appliances also commercially used, provided they fulfil the machine definition

DIN 7964 and REYHER article numbers 88151, 88152 and 88153

Product Safety Act (ProdSG)

The German Product Safety Act, formerly the Equipment and Product Safety Act (GPSG), applies whenever products are made available on the market, exhibited on the market or used for the first time in the context of a commercial activity as well as tot he erection and the operation of installations subject to mandatory inspection, which are used for commercial or economic purposes or which may put employees at risk, with the exception of installations subject to mandatory inspection.

The Product Safety Act (ProdSG) includes a number of regulations which have implemented a number of European directives into German law.

1. ProdSV – Regulation relating to making available on the market electrical equipment designed for use within certain voltage limits
2. ProdSV – Regulation relating to the safety of toys
6. ProdSV – Regulation relating to making available on the market simple pressure vessels
7. ProdSV – Appliances burning gaseous fuels regulation
8. ProdSV – Regulation relating to making available on the market personal protective equipment
9. ProdSV – Machinery regulation
10. ProdSV – Regulation relating to making available on the market recreation craft and transport using recreational craft
11. ProdSV – Explosion protection regulation
12. ProdSV – Lift regulation
13. ProdSV – Aerosol dispenser regulation
14. ProdSV – Pressure equipment regulation

EU Directive 97/23/EC
(Pressure equipment directive)

The EU Directive is implemented by the 6th and 14th ProdSV Regulation relating to making available on the market simple pressure vessels.

The Regulation is reflected in the Technical Regulations (standards), which include instructions on computation and construction, on approved materials (including materials and strength classes for bolts and nuts), on acceptance test provisions (factory inspection documents) and on selected and correspondingly recognised manufacturers.

In addition or if not otherwise specified, the Technical Regulations apply to bolts and nuts among others:

AD 2000 data sheet W 0 = General principles for materials
AD 2000 data sheet W 2 = For austenitic steel parts
AD 2000 data sheet W 7 = For ferritic steel parts
AD 2000 data sheet W 10 = For ferrous material parts for low temperatures

The recognised manufacturer of bolts and nuts made from permitted materials must prove to the responsible authority that the requirements have been satisfied according to AD 2000 data sheet W0. Manufacturers who fulfil these requirements are listed in the VdTÜV data sheet for materials 1253/1. These manufacturers are subject to constant inspection.
